A HANDY little diary and note book, which should be useful to students, has been issued by Messrs. Philip Harris and Co., Ltd., of Birmingham. It contains information as to the subjects and dates of the forthcoming examinations in connection with the Board of Education, City and Guilds of London Institute, &c.

MR. R. M. FERRIER, late lecturer in mechanical engineering at the Durham College of Science, Newcastle-upon-Tyne, has been appointed to the professorship of engineering at University College, Bristol, in the room of Dr. Stanton, whose appointment to the National Physical Laboratory was recently announced.

THE new laboratory and class rooms of the Muir Central College, Allahabad, described in a recent number of the *Pioneer Mail*, are in marked contrast to the rooms hitherto devoted to science in the institution. Judging from our contemporary's description, no pains have been spared to give the College sufficient accommodation and apparatus for the carrying on of scientific instruction.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, September 9.—M. Bouquet de la Grye in the chair.—Observations of the planet GQ, made at the Observatory of Algiers with the 0·318 metre equatorial, by M. F. Sy. The apparent positions of the planet, the positions of the comparison stars, and the magnitudes, were measured on the five nights August 21 to 26. The magnitude varied between 8·5 and 9·6.—On the existence of fundamental functions, by M. W. Stekloff.—On integral invariants, by M. Th. de Donder.—On the impossibility of representing by isophygmic curves the distribution of instability in a given seismic region, by M. F. de Montessus de Ballore. The author concludes that since seismic phenomena are essentially discontinuous both in time and space, the isophygmic curves can have no real existence. Proof of this is found in the paper by Oldham on the aftershocks of the great earthquake of June 12, 1897.—On the simultaneous appearance of mosquitoes of the genus Anopheles and the first cases of malarial fever in the region of Constantine, by M. A. Billet. The first cases of malaria occurring during the season were nearly simultaneous with the first appearance of the mosquito. The proof in one case of the presence of the malarial sporozoites in the Anopheles presents a particular interest.—On the biology of *Galeruca xanthomelaena*, by M. A. Menegaux.

TOWERS AND TANKS FOR WATER-SUPPLY.

Towers and Tanks for Water-Works. The Theory and Practice of their Design and Construction. By J. N. Hazlehurst. Pp. ix+216. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1901.) Price 10*s.* 6*d.*

THIS book deals exclusively with a special subject relating to water-supply, namely, the design and construction of metal stand-pipes and tanks for storing up water at a sufficient elevation to provide adequate pressure for its proper distribution. An illustration of a stand-pipe, 20 feet in diameter and 120 feet high, at St. Augustine, Florida, is given in the frontispiece; and a view of a high cylindrical tank raised on a tower, or more strictly a trestle, consisting of light metal standards braced together, erected for the water-supply of West Tampa, Florida, is shown opposite p. 116; and these two examples very fairly indicate the structures which form the subject of the volume. These stand-pipes and tanks, besides serving as reservoirs for the storage of an adequate supply of water to meet any sudden increased demand, and admitting of a temporary suspension of the pumping, are also valuable as regulators of the distribution, and as relief-valves for preventing the occurrence of undue stresses in the pipes in the process of pumping.

A considerable number of municipal water-works in the United States have been furnished with some form of metallic reservoirs, especially within recent years, in places where there is not a suitable site at a sufficient elevation for the construction of an ordinary reservoir of earth or masonry. Thus, out of more than three thousand complete municipal water-works in the United States, nine hundred and ninety-two have been equipped with elevated metallic reservoirs, five hundred and thirty-five of which have been erected since 1890. These structures exhibit great variety in their dimensions; for the largest tank in the United States, erected at Greenwich, Connecticut, in 1889, is made of wrought iron, 80 feet in diameter and 35 feet high, having a capacity of nearly 1,320,000 gallons, and rests on a concrete foundation; whilst a steel stand-pipe erected at Winona, Minnesota, in 1876, has a diameter of only 4 feet, and a height of 210 feet, with a capacity of 20,000 gallons, and rests upon a masonry foundation 18 feet thick.

Stand-pipes are by far the most common form of metallic reservoirs adopted in the United States, exceeding eight hundred in number; but steel tanks supported at the requisite height on steel trestles are now very often preferred, as a cheaper and safer way of supporting the effective upper column of water, 20 to 30 feet high, than by a column of water below enclosed in a cylinder; and already one hundred and sixty-one such tanks have been erected, most of them since 1890. The stand-pipes vary, for the most part, from 50 to 120 feet in height and from 11 to 39 feet in diameter, being exposed to maximum pressures of 82 to 130 lbs.; whilst their average dimensions and pressures are, 63 feet height, 20 feet diameter, with a capacity of 150,000 gallons, an ordinary pressure in the distributing pipes of 62 lbs. per square inch, and an emergency pressure of 104 lbs. The tanks, on the average, have a height of 37 feet, a diameter of 21⅓ feet, a capacity of 101,000 gallons, and an elevation on a trestle, or tower, of 63½ feet. To obtain the average pressure of 62 lbs., the effective height of the stand-pipe or tank would require to be 142 feet; but generally advantage can be taken of some natural elevation in the neighbourhood to reduce the actual height of the stand-pipe or tank. A chapter is devoted to the design of each of these structures, dealing also, in the case of stand-pipes with the bed-plate, connections, stiffener at the top against wind, and anchorage, and in the chapter on tanks, with wind-bracing and anchorage.

The author, however, leads up to the subject of design by five preliminary general chapters, on the chemical and physical properties of wrought iron and steel, the relative merits of these metals, the stability of structures, mechanical principles, and riveting; and after the two chapters on designing, he proceeds to deal, in three successive chapters, with foundations, painting, and shop-practice and erection. Accordingly, the book embraces a wider range of subjects than might be anticipated from its title; and by a very comprehensive treatment, a complete guide is provided for the design and construction of a special class of structures, of limited application, which have not hitherto received adequate consideration.

ELEMENTARY ZOOLOGY.

Animal Life: a First Book of Zoölogy. By President D. Starr Jordan, Ph.D., LL.D., and Prof. V. L. Kellogg, M.S. of Leland Stanford Junior University. Pp. ix+329. (London: H. Kimpton, 1901.)

THIS volume is one of the twentieth century text-book series, and adds another to the rapidly growing stock of elementary science manuals. It contains more than 300 pages, with 180 text figures, and its only novelty is the method of treatment, the authors combining the most elementary detail with the most abstruse ideas set forth in simple language. The reason of this is their conviction that "the veriest beginner ought to be an independent observer and thinker," and that "the point of view which the zoölogical beginner should take is the point of view that the best and most enlightened zoölogical scholar takes."

There are sixteen chapters to the book, with a brief classification and a glossary. The lives of the simple and the more complex organisms are first dealt with, then come chapters on multiplication and sex, on function and structure, on the life cycle, and so on. The struggle for existence, adaptation, commensalism and symbiosis, parasitism, protective resemblance, and other topics are all in turn considered, and the whole closes with a chapter on distribution.

There are incorporated in the book a selection of the elementary facts and the commonplaceisms of the modern fantasies of zoology. Both are reasonably dealt with, but we find nothing for very especial comment. Novelty mainly attaches to some of the illustrations; for example, the frontispiece—a photograph of a group of red-faced cormorants—a companion plate of a family of fur seals, a striking picture of the angler fish (Corynolophus) enticing its prey (not lighting up the sea-bottom this time !), an irresistible group of nestlings of the Canada jay, and a trio of manatees depicting three leading attitudes, make up a selection which is altogether admirable, and if for only these the book deserves support. On the contrary, however, illustrations such as those which do duty for a transverse section of a Hydra, for a tactile papilla and that of the calf's tongue, are beneath criticism; and doubtful to a degree are the incorporation in such a book as this, as all-typical, of such forms as Gonium, Calcolynthus, and Prophysema, about the latter two of which the less that is put before the elementary student the better. Old friends are with us, as, for example, the puss moth larva, with its "intensely exaggerated caricature of a vertebrate face." Anthropomorphic truly; but is this science?

We assume the authors would have the beginner read this book while prosecuting a more detailed study of individual forms, as with the now universal type-system. Its appearance within a year of Davenport's "Introduction to Zoology," a book of somewhat kindred aims, betokens a desire on the part of those responsible for the elementary scientific education of young America for a liberalising and humanising influence. The experiment is an interesting one, and it in some respects meets the ever-recurring question of the teacher, "What best can I give the student to read?" The lines on which the book is written appear to us risky in their great breadth and cursoriness; but while we await the result of experience before pronouncing further upon the book we admit that salient truths are expressed in a refreshingly familiar way, and that it is pleasant reading. The authors have fallen into the common error of according uneven recognition to authority, as, for example, in attributing the well-known series of drawings of Amœba to Schulze on p. 8, but not on p. 53, where at least a cross reference should have been inserted.

OUR BOOK SHELF.

Gustav Theodor Fechner. By W. Wundt. Pp. 92 (Leipzig: Engelmann, 1901.) Price 2*s*. net.

G. T. FECHNER, at once a distinguished and industrious devotee of exact research, and a poetic and religious enthusiast, is a most attractive figure in the history of German thought in the nineteenth century; and in the lecture delivered by Prof. Wundt before the Royal Society of Saxony in commemoration of the hundredth anniversary of his birth (April 19), the general reader will find a readable account of him which is composed with the double authority of a personal friend and colleague and of a successor.

The chief interest of the lecture itself lies in the proof that Fechner was first led to the psychophysical work by which he will be best remembered from a desire to find experimental confirmation for his poetico-philosophical theory of the universal animation and intelligence of physical nature.

Many readers will perhaps turn with most interest to the section of the appendix which contains the author's personal reminiscences of his famous predecessor. It is curious to learn from Prof. Wundt that Fechner's interest in the experimental psychology of which he was the originator was entirely confined to the problem of the so-called "logarithmic law" of psychophysical action, and that he could not be brought to read exact researches into other psychological questions. A. E. T.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Two Problems of Geometry.

IN your issue of August 22, Mr. A. B. Basset asks for solutions of the two problems, the trisection of an angle by means of the cissoid, and the duplication of the cube by the conchoid. I happened to come across a solution of the latter in an old book, Leslie's "Geometrical Analysis" (1821), where the problem is solved also in several other ways—by means of the cissoid, two parabolas, a rectangular hyperbola and circle, and the logarithmic curve. The problem of the trisection of an angle is also solved in several ways—by means of the conchoid (two ways), an hyperbola ($e = 2$) and intersecting circle, a rectangular hyperbola and circle, the quadratrix, the companion to the cycloid, and the Archimedean spiral, but *not* by the cissoid.

The problem of the duplication of the cube is solved in the following way by the conchoid.

Let AB, AC be the two given lines placed at right angles. Complete the rectangle AD and circumscribe a circle about it. Then if through C a line ECG be drawn cutting BD, BA produced in E and G and the circle again in H, and making EC = HG, it is known that AG and DE are the two mean proportionals between AC and AB. (Philo's construction.) Bisect BD at F, and on AB describe an isosceles triangle having BK = AK = BF. Join KG.

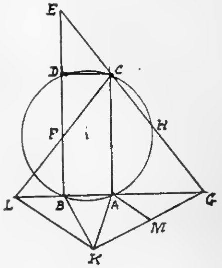

FIG. 1.

Then $ED \cdot EB = EC \cdot EH = GH \cdot GC = GA \cdot GB$,
$\therefore GA \cdot GB + BF^2 = ED \cdot EB + BF^2 = EF^2$;
and $GK^2 = AK^2 + GA \cdot GB = EF^2$, $\therefore GK = EF$.

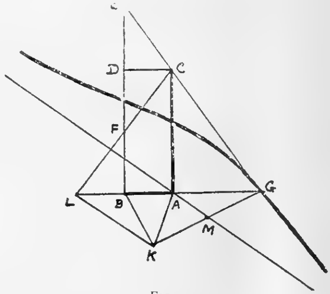

FIG. 2.

Join CF meeting AB produced in L, join LK and draw AM ∥ LK.

Then $LA = 2AB$, and $ED : BA = CA : AG$
$\therefore 2DE : AC = 2AB : AG = AL : AG$
$\therefore AL : AG = DE : DF$, $\therefore EF : DF = LG : AG$
$= GK : GM$; but $EF = GK$, $\therefore GM = DF = \frac{1}{2}AC$.

We have then the following construction.

With K as pole, AM as asymptote, and ½AC as the constant distance, describe a branch of a conchoid on the farther side of AM. Let BA cut the curve in G, then AG is the first, and KM the second mean proportional between AC and AB.

I have not been able to find any more recent accounts, but perhaps some others of your readers can tell whether the cissoid has been employed to trisect an angle, or whether it is possible to solve the problem by means of this curve. An easy solution, which is not given in Leslie's book, would be by means of the Limaçon, $r=a(1+2\cos\theta)$. D. M. Y. SOMMERVILLE.

24 Balhousie Street, Perth, August 24.

Auroræ and Meteors.

ON Tuesday, September 10, a beautiful display of the curtain Aurora Borealis was observed here at 9.30 p.m. It extended from the northern horizon to about 12°, and from north-by-east to north-north-west. The most brilliant part of the display lasted for about ten minutes after we first observed it, and then dissolved into a diffused, though vivid, glow. At 10.20 p.m. the Aurora was evidently much more distant, exhibiting itself as a brilliant glow above the north-western horizon.

At 9.52 p.m., the same evening, a brilliant meteor was observed darting towards the south-west, the line of motion passing between Corona Borealis and Hercules. The maximum brilliancy of the meteor was superior to that of Jupiter. At 10.45 p.m. a meteor was observed darting past Arcturus, which was then about 3° above the north-by-west point of the horizon. At 10.50 p.m. (Greenwich time) a brilliant meteor darted from a point within 1° of α Persei in a westerly direction, leaving a broad streak.

ALEX. C. HENDERSON.

The Manse, Rusness, Sanday, September 11.

THE INVERNESS EARTHQUAKE OF SEPTEMBER 18.

THE earthquakes of the Inverness district rank among the strongest ever felt in this country, but we must go back nearly a century to find one that surpassed the recent shock in intensity and extent of disturbed area. That of August 13, 1816, of which Sir T. Dick Lauder's brief but graphic account is the chief memorial left to us,[1] damaged several buildings in Inverness, and was felt over the whole of Scotland. After this, no shock of much consequence occurred until that of February 2, 1888, which was felt so far as Edinburgh and Glasgow and was perceptible over a district the area of which is estimated at about 15,000 square miles.[2] The earthquake of November 15, 1890, was slighter still; buildings were practically uninjured by it, and its disturbed area did not exceed 7500 square miles.[3] In all three cases the epicentre lay close to Inverness and not far from the northern boundary fault of the Highland district, and it is, therefore, natural that movements along this fault or system of faults should be held responsible for the origin of the earthquakes.

The shock of last week occurred shortly before 1.30 a.m., and thus it is possible that we may never know the full extent of its disturbed area. It does not seem to have been noticed in either Edinburgh or Glasgow, but the southern limit of the area cannot have lain many miles north of the line joining these cities, for the shock was certainly felt along the south coast of Fifeshire. Most of the rest of Scotland must have been sensibly shaken, for we have records from places as far north as Wick, in the west of Mull, and all along the east coast of Aberdeenshire.

In Inverness the damage, though never serious, is considerable in amount. There is scarcely a street in the town which has entirely escaped. In a few houses, chimney-stacks or parts of them fell down, and many chimney-cans were overthrown or displaced. For some miles round the town similar slight damage occurred. At Dochgarroch, about four miles south-west of Inverness, a long crack was formed in the north bank of the Caledonian canal. It is in the middle of the towing-path, in the hard-packed surface, and is nearly half an inch wide and about 600 yards long.

From the accounts which have appeared in the newspapers and from a few which I have already received, it is possible to draw roughly an isoseismal line corresponding to the degree 7 of the Rossi-Forel scale. This is in the form of an ellipse, with its longer axis parallel to the great fault and with the larger part of the curve lying on the south-east side of the fault. As the fault hades in this direction, it is exceedingly probable that a slip along it at no great depth gave rise to the recent earthquake.

The stronger Inverness earthquakes generally occur without the warning of preliminary shocks, but are followed for some time by weaker movements. Three at least occurred on the morning of the 18th, and it is not unlikely that for another month or so slight shocks may be felt in and around Inverness before the earth's crust there is once more brought to rest.

CHARLES DAVISON.

DR. J. L. W. THUDICUM.

THE death of Dr. Thudicum removes from our midst the living equivalent of a very familiar name. As a worker, to the younger generation of men of science he was not known, but some of his numerous communications upon topics extraordinarily varied can scarcely have escaped the observation, and have most probably received the serious attention, of almost every one interested in the medical sciences. More than half a century ago he graduated in medicine at Giessen. Almost immediately afterwards, stimulated by the work and magic influence of the great Liebig, who had attracted to the quiet and secluded university a bevy of young men eager to become adept in methods which, in the hands of their great master, had forced Nature to yield up truths of such momentous importance to physiology, Thudicum began to work at physiological chemistry.

Shortly afterwards he settled in this country, took a medical qualification and began to practise. It must be admitted that he established himself in London at an opportune moment. The application of exact chemical method to physiological, and certainly to pathological, phenomena was then in its infancy. The pupil of Liebig, trained in the methods of the Giessen laboratory and possessed of a practical knowledge of disease, had acres of virgin soil to cultivate. His power was soon appreciated; in 1856 he became physician to the St. Pancras Dispensary, and in 1858 lecturer to the Grosvenor Place School of Medicine. In 1865 he was appointed lecturer on pathological chemistry at St. Thomas' Hospital and director of a newly founded chemical and pathological laboratory there, obviously a position with immense opportunities.

His studies soon received official recognition, in that Sir John Simon, the principal medical officer to the Privy Council, engaged him in 1864 to undertake a series of researches upon pathological chemistry. Thudicum's results were embodied in reports which were published as appendices to the reports of the medical officers of the Privy Council and Local Government Board, and continued to appear at various dates down to 1882. Although no doubt a mass of constant work was embodied in these reports, they were not so fruitful in practical results as was anticipated, or perhaps it would be fairer to say, the tremendous achievements shortly afterwards of bacteriology in this department o hygiene, rendered them relatively insignificant. Further, these reports gave rise to a very considerable polemic, other workers in this field not accepting Thudicum's results, or, *a fortiori*, the theories founded upon them.

In 1871 Dr. Thudicum published conjointly with Dr. Dupré his most copious work, a book of 700 odd pages, on the origin, nature and varieties of wine. His views upon this subject have also not received general acceptance. In 1872 he published a manual of chemical physiology. His last work of note appeared in 1886 and consisted of a treatise on the chemical constitution of the brain.

Although Thudicum's life-study must be regarded as physiological chemistry, he from time to time wrote upon exclusively practical medical subjects, *inter alia* diseases of the nose, the curative value of electricity in medicine, &c., and consistently with this he made and kept together a large medical practice, being successful as a physician and greatly esteemed by his patients.

Thudicum's mind was one of problems, and whenever a problem esented itself to him he did his best—often, it is true, with imperfect methods—to solve it; even if, as in many cases must be admitted, his work has not yielded results of first importance, by his death medical science has lost at least an honest and indefatigable investigator and many men and women a sincere friend.

NOTES.

THE profound grief expressed by the British Association when news of the assassination of the late President of the United States was received, was described in last week's NATURE. We have now received a copy of the letter sent to Mr. Choate, the American Ambassador, by Prof. Rücker, president of the Association, and of the reply. The letter sent was as follows:—"To his Excellency the Hon. J. H. Choate, Ambassador of the United States of America. Sir,—The General Committee of the British Association for the Advancement of Science, assembled this year in Glasgow, desire me to express to you the horror with which they heard of the attack upon the late President of the United States, and their deep sorrow at his death. On the first day of the meeting in Glasgow the Association telegraphed to Mr. McKinley the assurance of their sympathy and of their earnest hopes for his recovery. These hopes have not been fulfilled, and it is now my sad duty to inform you that the tragic fate of the President of the United States has cast a deep shadow over our meeting. Together with all our fellow countrymen we share in the sorrow of the great sister-nation which you represent; and we desire, through you, to inform the men of science of America that the members of the British Association are bound to them not only by ties of blood, not only by the links which unite all students of Nature, but by the deeper feelings which draw together those who are partners in a common sorrow, and mourn one of the leaders of our common race.—I am, sir, your obedient servant, A. W. Rücker." In reply, the American Ambassador wrote:—"Sir,—I have received with heartfelt gratitude the kind expression of condolence and sympathy at the death of President McKinley which you have forwarded to me on behalf of the General Committee of the British Association for the Advancement of Science. I shall duly advise my Government of its receipt, and it will be highly appreciated by them and by Mrs. McKinley. Your kind message and hundreds of other similar communications from all parts of the British Dominions, carry an assurance of national friendship and goodwill which will be most welcome to the American people.—Yours sincerely, Joseph H. Choate."

MANY men of science will sympathise with Dr. Henry Woodward, F.R.S., at the sad death of his younger son, Mr. Martin Fountain Woodward, demonstrator in biology, Royal College of Science, South Kensington, London. Mr. Woodward was drowned on the night of September 15 by the capsizing of a boat at Moyard, near Letterfrack, co. Galway, Ireland, where he was in charge of the Marine Biological Laboratory of the Fisheries Board for Ireland, during the long vacation. He was in his thirty-sixth year.

DR. A. C. HADDON, F.R.S., sailed by the *Campania* on September 21 for a ten weeks' visit to the United States, for the purpose of studying the ethnological museums and the methods of instruction and research in ethnology in the States.

THE Swiney lectures this year will be delivered by Dr. J. S. Flett, on the "Geological Evidences of Former Geographical Conditions." The lectures will be delivered at the Victoria and Albert Museum, South Kensington, and will commence on Monday, October 7.

THE programme of the National Home-Reading Union for the thirteenth reading session, 1901–1902, includes nature-study among the subjects upon which advice will be given as to suitable books to read, and helpful articles will be contributed to the Society's magazine. Nature is, of course, the best teacher, but books are valuable in directing attention to her attractions. The address of the Society is Surrey House, Victoria Embankment, London, W.C.

WE regret to record the death of Dr. Edward Waller Claypole, B.A., F.G.S., of the Throop Polytechnic Institute, California, and previously professor at Antioch College, Yellow Springs, and at Buchtel College, Akron, in Ohio. In 1878 he drew attention to the discovery of the oldest known fossil tree from the Upper Silurian of Eaton, Ohio, and he named the specimen *Glyptodendron eatonense*. Since that date he contributed many papers to American journals on the geology and palæontology of the United States, giving a good deal of attento fossil fishes, but dealing with all branches of geological investigation.

ON Sunday, September 22, a solemn festival was held in the small Swedish island of Hveen. The occasion was the approaching 300th anniversary of the death of Tycho Brahe, the celebrated astronomer, who lived and worked on the island and spent his happiest years there. The festival was held among the few remains of Brahe's once imposing observatory at Uranienborg. The Copenhagen correspondent of the *Times* states that, early in the morning, guests from Denmark and Sweden, including representatives of the Universities, arrived in steamers. Outside the small harbour the Swedish ship *Drott* was at anchor with King Oscar on board. The King landed with the other guests and drove to Uranienborg. After Divine service, conducted by Bishop Billing, of Sweden, Dr. Hillebrandt, of Sweden, delivered a long speech, ending with the following words:—"We congratulate Denmark upon the never-dying memory of this man. This spot is now Swedish; therefore the King of Sweden is here to-day to honour the memory of Denmark's great and noble son." The party then walked through the ruins, which were decorated with the Swedish and Danish flags. The monument of Tycho Brahe, erected by Swedes, was decorated with the Danish colours.

PROF. ENGLER has returned from the Canary Islands with a large collection of plants for the Botanical Garden and Museum at Berlin.

MR. T. MEEHAN has an interesting paper, in the *Proceedings* of the Academy of Natural Sciences of Philadelphia, on the bending of branches in mature trees. The "weeping" habit is, according to him, always the result of diminished vitality in the tree.

IN the *International Bulletin* of the Academy of Sciences of Cracow (1901, No. 4), Godlewski and Polzeniusz have an exhaustive paper (in German) on the intramolecular respiration and production of alcohol in seeds placed in water. They conclude that the chemical processes which take place in the respiration of plants are not uniform, but may vary in different circumstances. In a general way they agree very closely with the process of fermentation.

AN International Conference on Plant Breeding and Hybridisation, to be held at New York in the autumn of 1902, is announced by the Horticultural Society of New York. The provisional programme includes the following papers, among others:—Results of hybridisation and plant breeding in Canada, by Mr. W. Saunders; notes on plant breeding in California, by Mr. E. J. Wickson; plant breeding in New Jersey, by Prof. B. D. Halsted; hybrid plums, by Mr. F. A. Waugh; variations in hybrids not appearing in the first generation, but later, by Mr. E. S. Goff; orchid hybrids, by Mr. Oakes Ames; cytological aspects of hybrids, by Mr. W. A. Cannon, Columbia University, New York City.

THE Bureau of Plant Industry of the United States Department of Agriculture has been entirely reorganised. The work has been divided into various groups, viz.:—Vegetable pathological and physiological investigations; botanical investigations and experiments; pomological investigations; grass and forage-plant investigations; experimental gardens and grounds; Arlington experimental farm; Congressional seed distribution; seed and plant introduction; tea culture experiments. Each class of investigations has its own laboratory, in charge of a skilled expert; the chief of the Bureau and head physiologist and pathologist is Prof. B. T. Galloway.

THE Reale Istituto Veneto announces nine prizes for competition in the faculties of science, letters and arts, for which essays have to be sent in at the close of the years 1901, 1902, 1903. The subjects in science include the projective properties of the two-dimensional algebraic surfaces of n dimensional space, the geophysical and biological characters of the lakes of the Venetian district excluding the Lago di Garda, and the development of the respiratory apparatus of the pulmonate vertebrata.

IN the *Physical Review* for August, Mr. Martin D. Atkins discusses the polarisation and internal resistance of electric cells. The object of the paper, of which a further part is promised, is to examine the two questions, firstly, is the change in the resistance of an electrolytic cell with varying currents a real or an apparent change? and, secondly, does the Wiederburg theory with its derived formulæ satisfy the known conditions and the characteristic curves of this change?

A SERIES of observations on the effects of Becquerel, Röntgen and other rays on the eye are detailed by Messrs. Himstedt and Nagel in the *Berichte* of the Freiburg Naturalists' Society (1901). The fact that such action exists was pointed out by Giesel. In the present investigations it is shown that the effects are in many cases largely due to fluorescence of neighbouring bodies, but that the rays appear to directly affect the rods of the retina. The authors also examined the effects of Röntgen rays and those from an incandescent lamp on the electromotive force set up in the eye of a frog, and the effects of the two kinds of rays are very similar.

WE have received a reprint of M. Guillaume's report communicated last year to the Physical Congress on the transitory deformations of solids. These variations, which differ from those attributed to elasticity or plasticity, are produced either by changes of temperature or by mechanical means, and M. Guillaume has studied them both in glass and in nickel steel. The author finds that the phenomena are governed by comparatively simple laws, and he considers that they may probably be attributed to variations in the chemical equilibrium of the molecules. The effects of the deformations in question in connection with the variations in thermometers render this subject one of practical interest.

THE Meteorological Society of Mauritius has commenced the issue of a new series of *Proceedings* and *Transactions*. Vol. i. embraces the five years 1896–1900, and contains a number of useful papers read before the Society—mostly drawn up by the secretary, and relating chiefly to the rainfall and cyclones in the South Indian Ocean. From want of funds and other causes no volume of *Transactions* has appeared since the year 1854, and it is pointed out in the preface to the present volume that whatever the Society may have accomplished in the past has been due, in a great measure, to the untiring energy of the late Dr. Meldrum, who contributed many papers on the law of storms; two of his investigations, on the form of cyclones and an atlas showing the cyclone tracks of the Southern Indian Ocean, have been included among the publications of the Meteorological Council. The present honorary secretary of the Society is Mr. T. F. Claxton.

WE have received a copy of a Report on the meteorological observations made at the Abbassia Observatory, Cairo, during the years 1898 and 1899, together with the mean results derived from the observations of the previous thirty years, prepared under the superintendence of Captain H. G. Lyons, R.E., Director-General of the Survey Department. In 1859, the Khedive ordered the reestablishment of the observatory which had existed from 1845–50 at Bulaq, but had then been closed; the site was not selected until 1865, and the series of regular observations only commenced in 1868. The observatory is situated about three miles north-north-east of Cairo, on the edge of the desert. Meteorological observations have been made every three hours, and magnetic observations have been taken recently, as frequently as the staff available for the purpose could be spared. In 1889, Mr. J. Barois published a very complete discussion of the climate of Cairo, and his tables have been used in the present report. All the observations have been made directly by the observers, but commencing with the year 1900, a complete set of self-recording apparatus has been brought into operation. The volume is accompanied by twenty-two plates showing the mean daily and annual variations of all elements; these greatly enhance the utility of the work, and show at a glance the general results derived from the detailed tabular statements, which are given in French measures. The discussion is a very valuable contribution to meteorological science, and both tables and plates are very carefully prepared and plainly printed.

THE October pilot chart of the North Atlantic and Mediterranean, just issued by the Meteorological Office, shows that during August and the early part of September there were scores of icebergs on the Belle Isle steamer route, from the 48th to the 56th meridian. One observer counted seventy-seven, another one hundred bergs, another described them as innumerable. Great numbers of them were very large, ranging up to a mile long and 200 feet high. No field ice was reported, but there were numerous low flat pieces of ice almost awash and dangerous to navigation. Some bergs were also fallen in with in the neighbourhood of the Flemish Cap, and a solitary one had wandered away to the south-westward of the Bank of Newfoundland to 43° N., 53° W. October witnesses a decided increase in the frequency and the strength of the gales experienced over the northern portion of the Atlantic, and in the remarks on the inset cyclonic type chart it is stated that during some part of the month, usually in about the middle, very severe gales are almost invariably experienced over the British Isles. Some of the most violent West Indian hurricanes on record have occurred in this month. It has been found convenient to divide the October tropical storms into two classes—those which are experienced during the existence of high barometric pressure over the Eastern States of America, and those when these anticyclones are away to the north or north-west. In the former case the hurricanes originate far out on the ocean, and their centres seldom pass to the westward of the 75th meridian, sometimes, indeed, their point of curvature is even so far to the eastward as 41° W., the mean path curving in 67° W. In the latter case most of the storms are developed about the Gulf of Mexico or the western end of the Caribbean Sea, and in their passage northward and north-eastward cling to the American coast, some a little way inland, others not far out at sea. Unlike the hurricanes of July, August and September, the distinguishing feature of the October ones is that they make comparatively little westing in the early stages of their career, their prevailing tendency being to draw away to the northward almost immediately after their formation, a fact which must be associated with the seasonal change in the disposition of pressure over America. The winds of the Adriatic, including the Bora and the Sirocco, are separately dealt with.

IN the *Zoologist* for September the Editor, Mr. W. L. Distant, inaugurates a discussion on "Animal Sense Perceptions," in the course of which he hints that colour-perception among the lower animals may be very different to our own, and consequently that we should be cautious in regarding many types of animal coloration as protective. Mr. E. Selous, in continuing his observations on the habits of the great crested grebe, hazards some very remarkable speculations.

IT was noted some months ago in this journal that an archaic type of arachnid from Texas belonging to the genus Kœnenia had been identified with the Sicilian *K. mirabilis*. Fuller comparison has enabled Miss A. Rucker to state in the *American Naturalist* for August that, as might have been expected, it turns out to be distinct. The genus has also been discovered in Siam and Paraguay, so that, like most archaic types, it is probably cosmopolitan. The material now available admits of the definition of the ordinal group to which this strange form belongs.

FROM the Smithsonian Institution we have received a copy of a paper by Messrs. Jordan and Snyder on the apodal or eel-like fishes of Japan, forming *Bulletin* No. 1239 of the U.S. Museum. The authors recognise two ordinal groups of these fishes, the one including the "rice-field eels" (Monopterus), and the other the true eels, congers and murænas. Many excellent illustrations are given, and a considerable number of new species described. For one genus the name Echidna is employed, and if this usage be correct the egg-laying mammal so designated requires a new title. In the British Museum Catalogue of Marsupials and Monotremes, Mr. O. Thomas definitely stated, however, that, as regards the eel, Echidna is a *nomen nudum*. The question should be decided one way or the other.

THE *Biologisches Centralblatt* of September 15 contains an account of Dr. K. Hescheler's investigations into the affinities of Pleurotomaria, that handsome genus of gastropod molluscs of which so few survivors now remain. Although the author confirms previous conclusions as to the generally primitive character of this genus, he finds that this does not hold good for all parts of its anatomy, which displays certain evidences of specialisation. In another communication Dr. Walkhoff contrasts the human lower jaw with that of the inferior Primates, in the course of which he points out that the celebrated "Naulette jaw" approximates to the modern type in a much greater degree than is the case with the one from Schipka, which is the oldest at present known.

TWO memoirs on development constitute the contents of the September issue of the *Quarterly Journal of Microscopical Science*. In the one Mr. J. G. Kerr continues his account of the developmental history of the South American lung-fish (*Lepidosiren paradoxa*), the first portion of which was published in the *Phil. Trans.* The author finds that both in this genus and the allied African Protopterus the early development is remarkably like that of the tailed amphibians, while it also resembles that of the lampreys, and rather less closely that of the so-called ganoid fishes. In the second article—illustrated with five double plates—Mr. R. Evans discusses in great detail the development of the Malayan representatives of peripatus, the description of which has been already noticed in these columns.

MR. ARTHUR SMITH, the curator of the Natural History Museum at Grimsby, is making a collection of notes and records of alien plants which occur in Britain, and asks the cooperation of local botanists.

MR. H. L. LYON reprints from the *Minnesota Botanical Studies* a paper entitled "Observations on the Embryology of *Nelumbo*," showing that both in its anatomy and in its embryology *Nelumbo* conforms to the type of the Monocotyledons. He derives from this the conclusion that the order Nymphæaceæ should be removed from the Dicotyledons and should be placed among Monocotyledons in the series Helobiæ.

IT is stated in the January-March 1901 issue of the Kew *Bulletin of Miscellaneous Information*, which has just reached us, that in consequence of the extreme pressure of the demands of important Government work the publication of the *Bulletin* had for a time to be suspended. Its issue has, however, now been resumed. The present number is almost entirely devoted to "a list of the contributors to the Herbarium of the Royal Botanic Gardens, Kew, brought down to December 31, 1899." The volume of the *Bulletin* for 1899 has also reached us. Its contents have been referred to in our "Notes" from time to time as the serial has appeared.

WE have received the Report of the Directors of the Botanical Survey of India for the year 1900-1901, also the Annual Report of the Royal Botanic Garden, Calcutta, for the year 1900-1901, and that of the Government Cinchona Plantation and Factory in Bengal for the year 1899-1900. In his report of the Royal Botanic Garden, Calcutta, the superintendent, Major Prain, speaks of the serious damage done by the excessive rainfall in the autumn of 1900, amounting to 40½ inches from the 19th to the 25th of September, 13⅓ inches having fallen on September 20. Although there was no wind, many trees were uprooted, and a large number of others died after the rain had ceased and they were exposed to sunshine. The Cinchona plantations were also greatly damaged by a disastrous rainstorm which passed over the Darjeeling district on the night of September 24-25, 1899. The most recent publication of the Botanical Survey of India (vol. i. No. 13) is the report of a botanical tour in the South Lushai Hills by Lieut. A. T. Gage.

THE Royal Horticultural Society has made a new departure in the August number of its *Journal*, in the form of "Notes on Recent Research." The design is to give in each issue an abstract or short digest of the papers of botanical, and especially of horticultural, interest in the leading British, Colonial, American, and Continental botanical journals. Of these abstracts several very good samples are given in the present number, the most important being a summary of Engler's valuable paper on plant distribution in the Alps. The abstracts from current horticultural periodicals occupy nearly fifty pages. Independently of these abstracts, the current number of the *Journal* is a very interesting one. Now that the phenomena of hybridisation are attracting so much attention, all students of the subject will be grateful to the editor for giving a full translation of Herr Gregor Mendel's much-quoted paper on "Experiments in Plant Hybridisation," published in 1865 in the *Abhandlungen des naturforschenden Vereines* in Brünn. The translator, Mr. W. Bateson, in an introductory note, gives the following as the chief outcome of Mendel's experiments:—"The proof that, in certain pairs of differentiating characters, the germ-cells of a hybrid, or cross-breed, are pure, being carriers and transmitters of either the one character or the other, not both." Other articles of interest in this bulky number are:—"Woad, a Prehistoric Pigment," by Dr. Plowright; "Wild Gardens," by H. S. Leonard; "Hybrid Conifers," by Dr. Masters; and others of special interest to horticulturists.

MRS. E. S. ARMITAGE read an interesting paper on some Yorkshire earthworks, before the British Association at Bradford, which has recently been published, with illustrations, in *The Reliquary and Illustrated Archaeologist* (vol. vii., July 1901, p. 158). The author holds that the very numerous artificial hillocks usually surrounded by a ditch and bank are not British, Roman, Scandinavian, or Saxon, as they have so often been described, but that they are Norman *mottes* which were protected round the top by a stockade and crowned with a wooden tower, the *bretarche* or *donjon*. These earthern castles were the local pivots which carried the action of the central machinery of Norman organisation into the remotest parts of the kingdom and thus established feudalism all over England.

AMONG the local *fêtes* of parts of the north of France the procession of giants forms the most original and picturesque custom. Each Flemish town formerly possessed its giant, but this curious custom preserves its ancient ceremonial in only a few localities. Lille has not seen for a long time the procession of the giant "Phinar," which was vilified as was its colleague "Annéen" at Valenciennes. The festivals of giants are still preserved at Dunkirk, where "Papa-Rœusse" is the idol of the inhabitants, at Cassel, at Gand, at Brussels, and especially at Douai, where every June "Gayant" has a triumphal procession accompanied by his wife, "Marie Cageon," and their three children, "Jacquot," "Fillon" and "Bimbin." An illustrated account of this interesting survival, by Paul Diffloth, will be found in *Cosmos* (Nouv. Série, No. 867, 1901, p. 292). A further account is given by Father R. P. Delattre of a Punic necropolis near Sainte-Monique, Senegal, West Africa. The numerous objects that are figured are deposited in the museum at Saint-Louis. This important investigation deserves the attention of English archæologists who are interested in the Mediterranean peoples.

THE Tuesday evening science lectures at the Royal Victoria Hall will commence on October 8, when Dr. A. Smith Woodward, F.R.S., will lecture on "Bone Digging in Greece." A lecture on "Photography in Natural Colours" will be given by Mr. J. W. Hinchley on October 15.

THE address delivered by M. E. T. Hamy, president of the French Association for the Advancement of Science, at the recent meeting at Ajaccio, appears in the *Revue Scientifique* of September 14. The subject is "Les debuts de l'anthropologie en France."

A LIST of second-hand electrical instruments and accessories and other apparatus required in laboratories has been sent to us by Mr. G. Bowron, Edgware Road, London. Teachers requiring efficient apparatus at a low cost, for lecture or laboratory purposes, might consult the list with advantage.

A COPY of the eighth annual report of the Church Society for the Promotion of Kindness to Animals has been received. The Society is distinguished from the generality of similar organisations in the fact that it directs attention to such subjects as the neglect of wounded war horses, the sufferings endured by horses used for war purposes, the carelessness and sickening brutality often exhibited in the slaughtering of animals, bearing reins, cruelty to wild animals in captivity, spurious sports, "angling" for song birds, and other cruelties to animals usually regarded with indifference. Many people are willing to assist the efforts of a society working in this direction who are unable to see why animals should not be inoculated in order to extend the means of alleviating human suffering. The office of the Society is at Church House, Westminster.

WE congratulate the authorities of the Government Museum of Madras on the Catalogue of the Prehistoric Antiquities, by R. Bruce Foote, which has just been published by the Superintendent of the Government Press, Madras, for the moderate sum of eight shillings. The catalogue is terse, and is illustrated by thirty-four plates of excellent photographic reproductions of some 225 objects and one plate of ownership marks on Iron-age pottery. It appears that there is in India a decided break between the Palæolithic and Neolithic ages, but in Southern India there is no gap in time between the Neolithic and Iron ages, the people of the latter age being doubtless direct descendants of the former. A few bronze, brass and copper implements and ornaments have been found, but apparently none as yet under circumstances showing distinctly that they preceded the Iron age. The existence of a distinct bronze or copper age may then, for the present, be regarded as quite problematic for South India. The pride of the Madras collection is unquestionably the great series brought together by the late Mr. James Wilkinson Breeks during his very successful exploration of the Nilgiri cairns and barrows while holding the post of Commissioner of those hills. A few palæoliths are figured, but no Neolithic implements or pottery. The Iron age is well illustrated in pottery and implements; one beautiful bronze vase of classical form and decorated with flutings and lotus designs deserves special mention. The archaic costumes of the figurines indicate that the art of iron smelting and working became known in India fully three thousand years ago, if not more.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus*, ♀) from India, presented by Mr. W. Openshaw; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by the Rev. E. P. Green; a Collared Peccary (*Dicotyles tajaçu*, ♂), a Ring-tailed Coati (*Nasua rufa*, ♀) from South America, presented by Mr. F. G. Newton, C.M.G.; a Ring-tailed Coati (*Nasua rufa*, ♀) from South America, two Punctated Agoutis (*Dasyprocta punctata*) from Central America, presented by Captain R. G. Taylor; a Hedgehog (*Erinaceus europaeus*), British, presented by Mr. C. J. Murray; a Fulvous-breasted Pied Woodpecker (*Dendrocopus macii*), two Jungle Babblers (*Crateropus canorus*), an Indian Cuckoo (*Cuculus micropterus*), a Pied Crested Cuckoo (*Coccystes jacobinus*), a Pied Ground Thrush (*Geocichla wardi*), a Crimson-breasted Barbet (*Xantholaema haematocephala*) from British India, presented by Mr. E. W. Harper; five Vipers (*Vipera berus*), British, presented by Mr. A. Old; a White-crowned Mangabey (*Cercocebus aethiops*) from West Africa, a Pigmy Marmoset (*Hapale pygmaea*) from the Upper Amazons, a Red-headed Marsh Bird (*Agelaeus ruficapillus*), two Black Tanagers (*Tachyphonus melaleucus*) from South America, a Yellow Sparrow (*Passer luteus*) from East Africa, an Indian Roller (*Coracias indica*) from India, two Gigantic Salamanders (*Megalobatrachus maximus*) from Japan, an Indian Elephant (*Elephas indicus*, ♀) from India, deposited; a Crab-eating Opossum (*Didelphys cancrivorus*) from Tropical America, purchased; an Altai Deer (*Cervus eustephanus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN OCTOBER.

Oct. 1. 11h. 14m. to 11h. 53m. Moon occults B.A.C. 1240 (mag. 5·7).
3. 17h. 10m. to 18h. 9m. Moon occults 71 Orionis (mag. 5·1).
11. 11h. 2m. Minimum of Algol (β Persei).
13. Ceres 7′ S. of γ Ceti (mag. 3).
13. 7h. Venus in conjunction with δ Scorpii. Venus 10′ N.
14. 7h. 51m. Minimum of Algol (β Persei).
15. Venus. Illuminated portion of disc = 0·705.
15. Mars. Illuminated portion of disc = 0·951.
17. 5h. 2m. to 5h. 38m. Moon occults ξ Ophiuchi (mag. 4·5).
19–21. Epoch of the Orionid meteors (radiant 91° + 15°).
22. 9h. 5m. to 9h. 7m. Moon occults c' Capricorni (mag. 5·2).
23. 4h. 44m. to 7h. 38m. Transit of Jupiter's Sat. IV.
23. 8h. 53m. to 10h. 6m. Moon occults κ Aquarii (mag. 5·5).
24. 14h. 35m. to 15h. 30m. Moon occults λ Piscium (mag. 4·7).
27. 2h. 25m. to 4h. 6m. Partial eclipse of the moon. Our satellite will rise at 4h. 35m., 29m. after the earth's shadow has passed off her disc, but the penumbra will remain until 5h. 26m., though it will be observed with difficulty.
28. Ceres in opposition to the sun (Ceres, mag. 7·4).
31. 12h. 44m. Minimum of Algol (β Persei).

FIREBALL OF SEPTEMBER 14, 1901.—Mr. W. F. Denning writes:—

"One of those brilliant fireballs which often appear suddenly in the early part of the night, and for a few seconds illumine the sky and landscape, was seen by many persons in various parts of the country on September 14 at about 8h. 44m. It was especially bright over the western part of England, and people in South Wales and North Devon obtained a fine view of the phenomenon. As seen from these parts, the fireball was many times brighter than Venus, and it moved with moderate slowness, leaving a strong trail or train of sparks, which, however, quickly died out. The head was bluish-white, and it seemed to plough its way through the atmosphere with an irregular motion and fluctuating light, as though strongly resisted.

"The fireball was well observed at Manchester, Wallingford (Berks), Chiddingfold (Surrey), Bristol and many other stations. The direction of its flight from the best descriptions was from between the constellations Aquarius and Pegasus, the radiant being at 345° + 1° near the star β Piscium. The height of the meteor when first seen was 66 miles vertically over a point 6 miles N.E. of Ilfracombe, North Devon, and when last seen the height was about 26 miles over a point in the sea 3 miles N.W. of St. David's Head, Pembrokeshire. The length of path was 83 miles and velocity about 20 miles per second. Possibly the path may have been longer and the object may have approached to within about 23 miles of the earth's surface, but the observations are not quite accordant. It is to be hoped that further descriptions of this splendid object will be forthcoming, so that the real path may be very accurately ascertained.

"On September 14, 1875, at 8h. 27½m., a large fireball passed over the eastern counties of England, falling from a height of 63 to 14 miles and directed from a radiant at 348° ± 0°. Lieut.-Colonel Tupman computed the real path from twelve accordant observations, and there is no doubt that this brilliant object, which appeared exactly twenty-six years ago, belonged to the same system as that which furnished the recent fireball. Apart from the large meteors which are often directed from it, the radiant is well defined every year from ordinary shooting stars, and it appears that its chief activity is displayed during the months of August and September."

NEW VARIABLE STAR 77, 1901, HERCULIS.—Dr. T. D. Anderson announces that he has detected variability in the star B.D. + 7°·3199, the position of which is

R.A. = 16h. 25m. 49·7s.
Decl. = + 7 8′·9.

Some years ago it was estimated to be about the ninth magnitude, while on August 19 and 21 it was invisible in a 3-inch finder with which tenth magnitude stars were easily visible.

THE GLASGOW MEETING OF THE BRITISH ASSOCIATION.

SECTION E.

GEOGRAPHY.

OPENING ADDRESS BY HUGH ROBERT MILL, D.SC., LL.D., F.R.S.E., F.R.G.S., PRESIDENT OF THE SECTION.

On Research in Geographical Science.

Introductory.

THE annual reassembling of friends and fellow-workers in the old re-visited towns, and the annual accession of new lovers of science, furnish a unique opportunity for a survey of the advances made in each department, a fitting occasion also for remembering those who have finished their work and can aid our deliberations only by the memory of their example.

Apart from our more intimate losses in the death of many distinguished geographers and devoted workers, the period since our last meeting has been for all a year of mourning. The passing of the nineteenth century was almost like the death of a friend, and it is still difficult to realise that the century which we had been so long in the habit of associating with everything new and great and progressive has itself become part of the past. Few coincidences have been more striking than the almost simultaneous close of that unparalleled reign which gave a name to the Era including all that was best and most characteristic of the century. The death of Queen Victoria carried so keen a sense of personal loss into every heart that few attempts have been made to show how vast a portion of the stream of time—measured by progress—intervened between the terminal dates of her life. Think for a moment of the splendid advances in the one small department of geographical exploration during the late Queen's reign, the multitude of landmarks which have been crowned by the great name of Victoria—of the Earth's most southerly land and its most northerly sea, of the largest lake and most majestic waterfall of Africa, the loftiest lake of Asia, the highest peak in New Guinea, the widest desert and most populous colony in Australia, and of the two thriving seaports on either side of the North Pacific which couple together the British Dominions of western America and eastern Asia.

What could be more appropriate in this first meeting after the close of such a century and of such a reign than to pass in brief but appreciative review the advances of geography during those hundred or those sixty-five years? One thing in my opinion is more appropriate than to dwell on past triumphs or to regret past greatness, and that is to survey our present position and look ahead. In the first year of a new century and of a new reign we are reminded that we have a future to face and that the world is before us, and I propose to seize this opportunity in order to speak of the science of geography as it is now understood and especially to urge the importance of the more systematic pursuit of geographical research henceforward.

Geography in the Universities.

The prospect of immediate expansion in many British universities seems at last likely to afford more than one opportunity of wiping out the old disgrace of the neglect of geographical science in the accredited seats of learning. Already Oxford has a well-manned School of Geography, and Cambridge has a Reader in Geography. The reconstituted University of London occupies the best position in the world for creating a chair of geographical research, situated as it is in the very centre of the comings and goings of all mankind, and in touch with the most complete geographical library and map-collection in existence. The new University of Birmingham may, it is hoped, prove better than its promises, and may perhaps after all provide some more adequate treatment of geography than its proposed partition amongst the professors of half a dozen special subjects, all of them concerned in geography, it is true, but none of them individually, nor all of them collectively, capable of embodying that coordination of parts into a harmonious unity which gives to geography its power as a mental discipline and its value for practical application. But England in all that pertains to higher education is still a poor country, and the will to do well is hampered by the grinning demon of poverty. Here, on the other side of the Border, we are in a different atmosphere. The wave of the magician's wand in the hands of Andrew Carnegie has brought wealth that last year would have been deemed fabulous to the ancient universities in Scotland, and it will be a disgrace to our country if this splendid generosity does not result in the establishment of one or more fully endowed and completely equipped chairs of geography.

There may still be some people who view geography as the concern only of soldiers and sailors, adventurous travellers, and perhaps of elementary teachers. Exploration is undoubtedly the first duty of geographers, but it is a duty which has been well done, the nineteenth century having left us only one problem of the first magnitude. This is the exploration of the polar regions, and even here the twentieth century clamours for new methods.

The Antarctic Expeditions.

This year has seen the long-hoped-for Antarctic expeditions set out on their great quest, a quest not only of new lands in the southern ice-world but of scientific information regarding all the conditions of the vast unknown region. Two expeditions have been planned in Great Britain and Germany with a complete interchange of information regarding equipment and methods of work. Provision has been made for simultaneous magnetic and meteorological observations, and in some instances for the use of instruments of identical construction, and all possibility of any unseemly rivalry in striving for the childish distinction of getting farthest south has been obviated by the friendly understanding that the British ship shall explore the already fairly known Ross quadrant, where it is pretty sure that extensive and accessible land will favour exploration by sledges, while the Germans have chosen the entirely unknown area of the Enderby quadrant which no ice-protected steamer has yet attempted to penetrate, and where they enter a region of potential discovery before they cross the Antarctic circle.

The British expedition is equipped on the good old plan that produced such fine results in the days of Cook and Ross; it is manned by sailors of the Royal Navy and is under the command of a gallant naval officer, though, unlike the earlier vessels, the *Discovery* is not herself a naval ship. As in the days of Cook the naval officers are assisted in their non-professional work by several young and promising scientific men, two of whom have already had experience of work in the polar regions. These have the great advantage of the counsel and help of Mr. George Murray, of the British Museum, who goes as far as Melbourne in the position of Director of the Scientific staff.

No one who has seen the zeal and unflagging enthusiasm with which Sir Clements Markham has organised the expedition can hesitate to accord to him in fullest measure the credit for its successful inauguration. And no one who has seen the quiet and good-humoured determination of the commander, Captain R. F. Scott, in overcoming many irritating preliminary difficulties, can doubt his fitness to undertake the heavy responsibilities of the voyage. I at least am sure that he will be a worthy successor to Cook, Ross, Franklin, Nares, and all the other officers who have made their names and the name of the British Navy famous in polar service. The second in command, Lieutenant Armitage, R.N.R., has had several years of Arctic experience, and amongst the crew there are some old whalers whose knowledge of the ways of sea-ice should prove of value. The ship and her equipment are unique; it is no exaggeration to say that she is the best-found and most comfortable vessel which has ever left our shores on a voyage of discovery.

The German expedition has been more boldly planned than ours. It is new and experimental all through, as befits a young nation in its first exuberant efforts in a new field. If some people suppose that it may have made mistakes that our expedition has avoided, these, at least, are new mistakes from which new lessons are to be learned. If risks must be run—and we of the twentieth century are, I trust, no more timid of incurring risks than our predecessors of the nineteenth, or the eighteenth, or even the seventeenth—it is good that they should be new risks. To scientific men in Germany it appears natural and reasonable that a man of science should be the head of a scientific expedition; and that a geographer should lead a geographical expedition. Many British men of science sympathise in this view. Dr. Erich von Drygalski, one of the professors of Geography in the University of Berlin, has been entrusted with the command to which he was appointed before the ship was designed, and for five years he has given all his time and thought to the expedition. He is supported by a band of highly trained specialists, who have spared neither time nor travel in mastering the subjects with which they may deal, and each has also received a general training in the subjects of all his colleagues—an admirable precaution. The captain of the *Gauss*, who belongs to the Merchant Service, has taken a course of training from the Norwegian whalers off Spitsbergen. He will, of course, be absolute master of the ship and crew in all that concerns order and safety, but he will be under the direction of the leader in all that concerns the plan of the voyage and the execution of scientific work. This arrangement is one which has always seemed to me to be desirable, that the captain of a ship on scientific service should occupy a position in relation to the scientific chief similar to that of the captain of a yacht in relation to the owner; but it is subject to the drawback that a naval officer could not well be asked to accept such a divided command.

But whatever our views as to ideal organisation may be, we are all certain that both expeditions will do the utmost that they can to justify the confidence that is placed in them and to bring honour to their flags. We know that the officers and staff of the *Discovery* belong to a race which, whether trained in the University or in the Navy, has acquired the habit of bringing back splendid results from any quest that is undertaken.

A Definition of Geography.

The bright prospects of Antarctic Exploration must not, however, blind us to the fact that exploration is not geography, nor is the reading or even the writing of text-books, nor is the making of maps, despite the recognition of leading cartographers as "Geographers to the King." These are amongst the departments of geography, but the whole is greater than its parts.

The view of the scope and content of Geography which I have arrived at as the result of much work and some little reading during twenty years is substantially that held by most modern geographers. But it is right to point out that the mode of expressing it may not be accepted without amendment by any of the recognised leaders of the science, and for my own part I believe that discussion rather than acceptance is the best fate that can befall any attempt at stating scientific truth.

Put in the fewest words, my opinion is that

Geography is the science which deals with the forms of relief of the Earth's crust, and with the influence which these forms exercise on the distribution of all other phenomena.

This definition looks to the form and composition of the Earth's crust itself, and to the successive coverings, partial and complete, in which the stony globe is wrapped. We sometimes hear of the New Geography, but I think it is more profitable to consider the present position of Geography as the outcome of the thought and labours of an unbroken chain of workers, continuously modified by the growth of knowledge, yet old in aim, old even in the expression of many of the ideas that we are apt to consider the most modern.

Some Historical Landmarks.

Claudius Ptolemæus, about 150 A.D., gathered into his great "Geography" the whole outcome of the Greek study of the habitable world. He laid stress on the threefold nature of descriptions of the Earth's surface, the general sketch of the great features of the world alone receiving the name of Geography, the more special description of an area he termed Chorography, and the detailed account of a particular place Topography.

Aristotle, who first adduced real proofs of the sphericity of the Earth, had not failed to note the relationships which exist between plants and animals, and the places in which they are found, and he argued that the character of peoples was influenced by the land in which they lived; but Ptolemy cared little for theories, comparisons, or relationships, confining himself rather to the record of actual facts. He made errors, the results of which were more important, as it happened, in advancing knowledge than were the truths which he recorded; for after the troubled mediæval sleep, when even the spherical form of the Earth was blotted out of the knowledge of Christendom, the scientific deductions made by Toscanelli from the false premises of Ptolemy heartened Columbus for his westward voyage to the Indies, on the very outset of which he stumbled all unknowing on the New World. When Magellan succeeded in the enterprise which Columbus had commenced, the fourteen centuries' reign of Ptolemy in geography came to an end; his work was done.

The rapid unveiling of the Earth in the sixteenth and seventeenth centuries cast a glamour over feats of exploration which has not yet been wholly dissipated, and it may not be easy, even now, to obtain wide credence for the fact that the explorer is usually but the collector of raw material for the geographer.

It is of vital interest to trace the re-formation of the theory of geography after its interruption in the Middle Ages. The fragments of the old Greek lore were cemented together by new and plastic thoughts, crudely enough by Apian, Gemma Frisius, and Sebastian Munster in the sixteenth century, but with increasing strength and completeness by Cluverius, Carpenter, and Varenius in the seventeenth.

The First Oxford Geographer.

The names of Cluverius and Varenius are familiar to every historian of geography, but that of Carpenter, I am afraid, is now brought to the notice of many geographical students for the first time. He was not so great as Varenius, but he was the first British geographer to write on theoretical geography as distinguished from mathematical treatises on navigation or the repetition of narratives of travel, and I think that there is evidence to show that his work had an influence on his great Dutch contemporary.

Nathanael Carpenter, Fellow of Exeter College, Oxford, published his book in 1625 under the title—

"Geographie delineated forth in two Bookes. Containing the Sphericall and Topicall parts thereof," and with the motto from Ecclesiastes on its title-page—

"One generation commeth, and another goeth, but the Earth remayneth for ever."

The great merits of Carpenter's treatise are his firm grasp of the relation of one part of geography to another, his skilful blending of the solid part of the work of Aristotle and Ptolemy with that of the explorers and investigators of his own generation, and the wholesome common-sense that dominates his reasoning. His definition is comprehensive and precise.

"Geographie is a science which teacheth the description of the whole Earth. The Nature of *Geographie* is well expressed in the name: For *Geographie* resolved according to the *Greeke* Etymologie signifieth as much as a description of the Earth; so that it differs from *Cosmographie*, as a part from the whole. Forasmuch as *Cosmographie* according to the name is a description of the whole world, comprehending under it as well *Geographie* as *Astronomie*. Howbeit, I confesse, that amongst the ancient Writers, *Cosmographie* has been taken for one and the self-same science with *Geographie* as may appeare by sundry treatises meerely Geographicall, yet intituled by the name of *Cosmographie.*"

The differences held by Ptolemy to distinguish geography from chorography Carpenter shows to be merely accidental, not essential, and as to geography he says "It is properly tearmed a *Science*, because it proposeth to it selfe no other end but knowledge; whereas those faculties are commonly tearmed *Arts*, which are not contented with a bare knowledge or speculation, but are directed to some farther work or action. But here a doubt seems to arise, whether this *Science* be to be esteemed *Physicall* or *Mathematicall*? Wee answer, that in a Science two things are to bee considered: first, the *matter* or object whereabout it is conversant; secondly, the *manner* of handling and explication: For the former no doubt can bee made but that the object in *Geographie* is for the most part *Physicall* consisting of the parts whereof the Spheare is composed; but for the manner of Explication it is not *pure* but *mixt*; as in the former part *Mathematicall*, in the second rather *Historicall*; whence the whole Science may be alike tearmed both *Mathematicall* and *Historicall*; not in respect of the *subject* which we have said to be *Physicall* but in the manner of *Explication.*"

Although somewhat diffuse in expression, the meaning of these statements is clear and sound, and to the British public as new now as it was in the days of King Charles. The book treats of mathematical geography and cartography, of magnetism, climates, the nature of places, of hydrography, including the sea, rivers, lakes and fountains, of mountains, valleys and woods, of islands and continents, and at considerable length of people and the way in which they are influenced by the land in which they live. Whether Dr. Carpenter lectured on geography in Oxford I do not know, but his book must have acquired a certain currency, for a second edition appeared in 1635, and it seems probable that it was known to Varenius.

Varenius and Newton.

Varenius, a young man who died at twenty-eight, produced in Latin a single small volume published in 1650, which is a model of conciseness of expression and logical arrangement well worthy even now of literal translation into English. So highly was it thought of at the time that Sir Isaac Newton brought out an annotated Latin edition at Cambridge in 1672.[1] The opening definition as rendered in the English translation of 1733 (a work spoilt in most places by a parasitic growth of notes and interpolations) runs:—

"Geography is that part of *mixed mathematics* which explains the state of the earth and of its parts, depending on quantity, viz. its figure, place, magnitude and motion with the celestial appearances, &c. By some it is taken in too limited a sense, for a bare description of the several countries; and by others too extensively, who along with such a description would have their political constitution."

Varenius produced a framework of Physical Geography capable of including new facts of discovery as they arose, and it is no wonder that his work, although but a part, ruled unchallenged as the standard text-book of pure geography for more than a century. He laid stress on the causes and effects of phenomena as well as the mere fact of their occurrence, and he clearly recognised the vast importance upon different distributions of the vertical relief of the land. He did not treat of human relations in geography, but, under protest, gave a scheme for discussing them as a concession to popular demands.

Kant.

As Isaac Newton, the mathematician, had turned his attention to geography at Cambridge in the earlier part of the eighteenth century, so Immanuel Kant, the philosopher, lectured on the same subject at Königsberg in the later part. The fame of Kant as a metaphysician has defrauded him of much of the honour that is his due as a man of science. As Prof. Hastie puts it: "His earlier scientific work, like an inner planet merged in light, was thus almost entirely lost sight of in the blaze of his later philosophical splendour."

Kant, it will be remembered, considered that the communication of experience from one person to another fell into two categories, the historical and the geographical: that is to say, descriptions in order of time or in order of space. The science of geography he considered to be fundamentally physical, but physical geography formed the introduction and key to all other possible geographies, of which he enumerated five: *mathematical*, concerned with the form, size, and movements of the earth and its place in the solar system; *moral*, taking account of the customs and characters of mankind according to their physical surroundings; *political*, concerning the divisions of the land into the territories of organised governments; *mercantile*, or, as we now call it, commercial geography; and *theological*, which took account of the distribution of religions. It is not so much the cleavage of geography into five branches, all springing from physical geography like the fingers from a hand, which is worthy of remark, but rather the recognition of the interaction of the conditions of physical geography with all other geographical conditions. The scheme of geography thus acquired a unity and a flexibility which it had not previously attained, but Kant's views have never received wide recognition. If his geographical lectures have been translated no English or French edition has come under my notice, and such currency as they obtained in Germany was checked by the more concrete and brilliant work of Humboldt, and the teleological system elaborated in overwhelming detail by Ritter.

The teleological views of Ritter were substantially those of Paley. The world, he found, fitted its inhabitants so well that it was obviously made for them down to the minutest detail. The theory was one peculiarly acceptable in the early decades of the nineteenth century, and it had the immensely important result of leading men to view the earth as a great unit with all its parts coordinated to one end. It gave a philosophical, we may even say a theological, character to the study of geography.

Kant's views had pointed to such a unity, but from another side, that of evolution. It was not till after Charles Darwin had fully restored the doctrine of evolution to modern thought that it was forced upon thinking men that the fitness of the earth to its inhabitants might result, not from its being made for them, but from their having been shaped by it. It is certain that the influence of the terrestrial environment upon the life of

[1] Dugdale, in the introduction to the English translation published in 1733, states explicitly that Newton produced his version for the benefit of the students attending his lectures "on the same subject" from the Lucasian chair; but we have been unable to find any more satisfactory evidence that Newton actually lectured on geography at Cambridge.

a people has been carried too far by some writers—by Buckle, in his "History of Civilisation," for example—but it is no less certain that this influence is a potent one.

The Nature of Geography.

Granted that such influence is exercised, some objectors may urge that geography has nothing to do with the matter, and we are compelled to acknowledge that the meaning and contents of geography are in this country as variously interpreted as the colour of the chameleon in the traveller's tale. Yet my thesis is that it is just this relation between the forms of the solid crust of the Earth and all the other phenomena of the surface that constitutes the very essence of geography.

It is a fact that many branches of the study of the Earth's surface which were included in the cosmography of the sixteenth century, the physiography of Linnæus, the physical geography of Humboldt, and perhaps even the *Erdkunde* of Ritter, have been elaborated by specialists into studies which, for their full comprehension, require the whole attention of the student. Geology, meteorology, oceanography and anthropology, for example, have been successively specialised out of geography; but it does not follow that these specialisations fully occupy the place of geography, for that place is to coordinate and correlate all the special facts concerned so that they may throw light on the plan and the processes of the Earth and its inhabitants. Geography, in fact, is concerned with the results, not with the processes of the special sciences, and the limits between geography and geology, to take a single instance, are to be drawn, not between any one class of phenomena and another, but between one way and another of marshalling and utilising the same facts. This was clear to Carpenter in 1625, though we have almost forgotten both it and him.

The Principles of Geography.

The principles of geography—the "pleasant principles," to use the phrase of old William Cuningham in 1559—on which its claims to status as a science rest are generally agreed upon by modern geographers, though with such variations as arise from differences of standpoint and of mental process. The evolutionary idea is unifying geography as it has unified biology, and the whole complicated subject may be presented as the result of continuous progressive change brought about and guided by the influence of external conditions. These views have been often expressed in recent years, but they do not seem to have been very seriously considered, and no excuse need be offered for presenting them once more, though in an epitome curt to baldness.

The science of geography is of course based on the mathematical properties of a rotating sphere; but if we define geography as the exact and organised knowledge of the distribution of phenomena on the surface of the Earth, we see the force of Kant's classification, which subordinated mathematical to physical geography. The vertical relief of the Earth's crust shows us the grand and fundamental contrast between the oceanic hollow and the continental ridges; and the hydrosphere is so guided by gravitation as to fill the hollow and rise upon the slopes of the ridges to a height depending on its volume, thus introducing the great superficial separation into land and sea. The movements of the water of the ocean are guided in every particular by the relief of the sea-bed and the configuration of the coast lines. Even the distribution of the atmosphere over the Earth's surface is affected by the relief of the crust, the direction and force of the winds being largely dominated by the form of the land over which they blow. The different physical constitution of land, water and air, especially the great difference between the specific heat and conductivity or diathermancy of the three, causes changes in the distribution of the sun's heat, and as a result the simple climatic zones and rhythmic seasons of the mathematical sphere are distorted out of all their primitive simplicity. The whole irregular distribution of rainfall and aridity, of permanent, seasonable and variable winds, of sea-climate and land-climate, is the resultant of the guiding action of land forms on the air and water currents, disturbed in this way from their primitive theoretical circulation. So far we see the surface forms of the Earth, themselves largely the result of the action of climatic forces, and constantly undergoing change in a definite direction, controlling the two great systems of fluid circulation. These in turn control the distribution of plants and animals, in conjunction with the direct action of surface relief, the natural regions and climatic belts dictating the distribution of living creatures. A more complicated state of things is found when the combined physical and biological environment is studied in its incidence on the distribution of the human race, the areas of human settlement, and the lines of human communications. The complication arises partly from the fact that each of the successive earlier environments acts both independently and collectively; but the difficulty is in greater degree due to the circumstance that man alone amongst animals is capable of reacting on his environment and deliberately modifying the conditions which control him.

It seems to me that the glory of geography as a science, the fascination of geography as a study, and the value of geography in practical affairs are all due to the recognition of this unifying influence of surface relief in controlling, though in the higher developments rather by suggestion than dictation, the incidence of every mobile distribution on the Earth's surface.

The Classification of Geography.

Following out this idea, we are led to a classification of the field of geography in a natural order, in which every department arises out of the preceding with no absolute line of demarcation, and merges into the succeeding in the same way. This classification, it is necessary to note, is not like a series of pigeon-holes, which may be placed in any arbitrary order, but like a chain, in which the succession of the links is essential and unalterable.

Since form and dimension are the first and fundamental concepts in geography, the first and basal division is the *Mathematical.* Mathematical geography leaves the Earth as a spinning ball lighted and warmed according to a rigid succession of diurnal and annual changes. This merges into the domain of *Physical Geography*, which involves the results of contemporary change in the crust and the circulation of the fluid envelopes, with the resulting modifications in the simple and predictable mathematical distributions. This division falls naturally into three parts: Geomorphology, dealing with the forms of the solid crust and the changes they are undergoing at the present time; Oceanography, dealing with the great masses of water in the world; and Climatology, dealing with the effects of solar energy in the air. But all three spheres—lithosphere, hydrosphere, and atmosphere—are so closely inter-related that no one of them can be studied without some preliminary knowledge of the others. This forms the largest and most important part of geography, more varied and intricate than the mathematical, better known and more definite than those involving life.

Bio-geography, the geographical distribution of life, arises directly from physical geography, which dominates it, but it is full of complex questions which involve the biological nature of the organism and the influence of physical environment, in which geographical elements, although predominant, do not act alone. Difficult as some of the problems of the distribution of life are at the present day, the remains of living creatures found fossil in the rocks, and the survivors of archaic forms still lingering in remote islands, supply us with our only instrument of research into the geography of past ages, often making it possible to lay down the areas of land and water in earlier geological periods.

The relation of man to the surface of the Earth detaches itself from the rest of Bio-geography by the number of exceptions to general laws of distribution and by the human power of modifying environment. It has necessarily been formed into a special department, *Anthropo-geography.* In primitive man the control exercised by environment is nearly as complete and simple as in the case of the lower animals; but with every advance in culture fresh complications are introduced. The relation of people to the land they inhabit, the choice of sites for dwellings and towns, the planning and carrying into effect of lines of communication, are all obviously much under the control of land form and climate. When people get settled in a favourable position they usually become attached to it; they acquire, one may say, the colour of the land, in modes of thought as well as in manner of life. The poems of Ossian and the Crofter Question require for their elucidation a knowledge of the geographical conditions of the Western Highlands, just as the Border ballads and the Border raids were largely conditioned by the geography of the Southern Uplands.

Attachment to the native valley or the native fields leads to the holding of land by clans or tribes and the fusion of tribes into nations, while changes in physical conditions stimulating migration from a deteriorating country may lead to the invasion of settled territories by homeless hordes. Here Anthropo-geography buds off the subdivision of *Political Geography*, which takes account of the artificial boundaries separating or sub-dividing countries, and of the innumerable artificial restrictions and ameliorations which are superimposed on the natural barriers and channels of intercommunication. Even in political geography only a humble place is held by a statement of boundaries and capitals, to lists of which the great name of Geography has actually been confined by people who ought to have known better.

Anthropo-geography views the world from the standpoint of the race, political geography from the standpoint of the nation; but room has to be found for a yet more restricted outlook, that of the individual, whose view of the world as it profits himself is known as commercial geography. This department deals with natural commodities and their interchange, and perhaps because here rather than in the other departments a successful comprehension of the inter-relation of cause and effect may be, in the language of the schoolroom, "reduced to pounds, shillings and pence," the name of Applied Geography has been proposed. It fitly terminates our survey of the science, for the flickering disturbances of the equilibrium of supply and demand known simultaneously over the whole world, and the slower movements of transport to restore equilibrium, are still far from the power of scientific prevision, and all we can do at present is to point out certain clear lines of least resistance, or greatest advantage, due to the interactions of natural and human causes and effects.

To sum up in a sentence the field and the function of geography in the broad majesty of its completeness, we may say that it is the description of the surface of the solid Earth as it is in itself, as it acts upon the ocean, the air, and the living things which inhabit it, and as it is affected in turn by their actions.

Geography and the State.

Viewed thus, I believe that geography will be found to afford an important clue to the solution of every problem affecting the mutual relations of land and people, enlightening the course of history, anticipating the trend of political movements, indicating the direction of sound industrial and commercial development.

It would be possible, unfortunately it would be easy, to enumerate misconceptions of history, blunders in boundary settlements, errors in foreign policy, useless and wasteful wars, mistakes in legislation, failures in commercial enterprise, lost opportunities in every sphere, which are due to the neglect of such a theoretical geography. Surely it is to the laws defining the interaction of Nature and Man that we should turn for guidance in such affairs rather than to the dull old British doctrine of "muddling through." That vaunted process after all means that we are driven by stress of facts to do without intending it or knowing how, and at immense expense, the very things that intelligent study beforehand would have shown to be necessary, feasible and cheap.

All this has been urged again and again, and it has fallen on the ears of those in authority "like a tale of little meaning, though the words are strong." I admit that all advocates of a rational geography have not escaped the danger of the special pleader—they have promised too much. If a Government official were to say, "Yes, I confess there was a mistake here, the affair was managed badly, much money and some prestige were lost; it must all be done over again; please tell me how," I am afraid that the chances are that the answer would be vague, general and unpractical. If the answer to this boldly hypothetical question is ever to be clear and definite, geography must be studied as it has never yet been studied in this country. It must pass beyond the stage of a pastime for retired officers, colonial officials and persons of leisure, and become the object of intense whole-hearted and original study by men of no less ability who are willing to devote, not their leisure, but their whole time to the work. The object of geographical research should be nothing less than the demonstration or refutation of what we claim to be the central principle of geography—that the forms of terrestrial relief control all mobile distributions.

A Projected Geographical Description.

In order to focus the question it may be convenient to consider the geography—or chorography, as Ptolemy would have termed it—of the British Islands. No author has ever attempted to give such a description. Camden's "Britannia" was swamped by archæology; the county histories, which are certainly not deficient in number, were wrecked outward bound on the harbour-bar of genealogy. Sir John Sinclair's old "Statistical Account of Scotland" in the intelligent utilisation of very incomplete data was a great but solitary stride in the right direction. Bartholomew's great "Atlas of Scotland" supplies the cartographical basis for a modern description of the northern kingdom; but the description itself has not been undertaken on an equal scale. The work of producing a complete geographical description of the British Islands would be gigantic, but not hopelessly difficult.

The material has been collected at an enormous expenditure of public money, and is stacked more or less accessibly, much of it well-seasoned, some I fear spoilt by keeping; but there it lies in overwhelming abundance, heaps of building materials, but requiring the labour of the builder before it can become a building.

There is first and chief the Ordnance Survey, one of the grandest pieces of work in mathematical geography that has ever been accomplished. The result is a series of maps almost as perfect as one can expect any human work to be, showing in a variety of scales from ¼ of an inch to 25 inches to a mile every feature of the configuration of the land—except the lake-beds.

There is next the hydrographic survey by the Admiralty, giving every detail of the subaqueous configuration in and around our islands—except the lake-beds.

These two great surveys supply the basis for a complete description of the British Islands, and the geological survey, which in a sense is more elaborate than either of the others, completes the fundamental part. The geological map makes it possible to explain many of the forms of the land by referring to the structure of the rocks which compose them. Both the geological and hydrographic surveys are accompanied by memoirs describing the features and discussing the various questions arising from the character of each sheet; but there is nothing of the kind for the maps of the ordnance survey.

The ordnance maps show at the date of their preparation the extent and also the nature of the woodlands and moorlands, and this information is supplemented by the Returns of the Board of Agriculture, which each year contain the statistics of farm crops, waste land, and livestock for every county. These returns are excellently edited from the statistical point of view, but they are not discussed geographically. It is easy to see in any year how much wheat is raised in each county, but it is a slow and laborious process to discover from the Returns what are the chief wheat-growing areas of the country. The county is too large a unit for geographical study, as it usually includes many types of land form and of geological formation. Before the distribution of crops can be understood or compared with the features of the ground they must be broken up into parishes, or even smaller units, and the results placed on maps and generalised. The vast labour of collecting and printing the data is undertaken by Government, and paid for by the people without a murmur, but the geographer is left in ignorance for the want of a comparatively cheap and simple cartographic representation of the facts.

The Inspector of Mines and the Board of Trade publish statistics of the industry and the commerce of the country, statistically excellent, no doubt, but in most cases lacking the cartographic expression which makes it possible to take in the general state of the country from year to year. The same is true of the Registrar-General's Returns of births, marriages, and deaths, in themselves an admirable epitome of the health conditions of the country, and of the fluctuations in population, but limited by a narrow specialism to the one purpose.

Finally and chiefly we have the Census Reports. Once in ten years the people are numbered and described by sex, age and occupation. The inhabited houses are numbered, and the smaller dwellings grouped according to size. The figures are most elaborately classified and discussed, so as to bring out the distribution of population, and its change from the previous decade. But to the geographer the Census Reports are like a cornfield to a seeker of bread. The grains must be gathered, prepared, and elaborated before the desired result is obtained. Nowhere is the cartographic method more useful than here. It is a striking contrast to turn to the splendid volumes of the United States Census Reports, many of them statistically inferior to ours, but thickly illustrated with maps, showing at a glance the distribution of every condition which is dealt with, and enabling one to follow decade by decade the progressive development of the country, and to study for each census the relations between the various conditions.

These are only a few of the statistical publications, produced by Government, and embodying year after year a mass of conscientious labour, which, save for a few specialists who extract and utilise what concerns themselves, is annually "cast as rubbish to the void."

One small department supported by public money, but under unofficial direction, may be referred to as an example of the successful employment of cartographic methods. This is the Meteorological Council, appointed by the Royal Society, and charged with the collection of meteorological data and the publication of weather reports, forecasts, and storm warnings. The maps published twice daily to show the distribution of atmospheric pressure and temperature are only rough sketches and very much generalised, yet they serve the purpose of presenting the facts in a graphic form, yielding at a glance information which could only be extracted from tables by long and laborious efforts. The pilot charts, published monthly by the same department, showing the average conditions of air and sea over the whole North Atlantic, and the occasional atlases of oceanographical data are valuable geographical material.

The official work of Government is supplemented by the voluntary labours of many societies, in whose transactions much valuable material is stored, and in not a few cases is admirably discussed. But even with these supplements gaps remain which must be filled by private enterprise before a complete geographical description can be compiled.

Considering the Ordnance Survey alone it is hardly credible and not at all creditable that the Treasury should veto the extension of the survey to the lake-beds on the score of expense, yet such is the fact. The directors of the Survey have shown themselves ready to encourage private workers by placing the data presented by them upon the maps with due acknowledgment.

The Survey of the Lakes.

It is with profound satisfaction that I now make an announcement—by special favour the first public announcement—of a scheme of geographical research on a national scale by private enterprise. Sir John Murray and Mr. Laurence Pullar have resolved to complete the bathymetrical survey of all the fresh-water lakes of the British Islands. Mr. Laurence Pullar will take an active part in the proposed survey, and has made over to trustees a sum of money sufficient to enable the investigation to be commenced forthwith and to be carried through in a comprehensive and thorough manner. It is intended to make the finished work an appropriate and worthy memorial of Mr. Pullar's son, the late Mr. Fred Pullar, who had entered enthusiastically upon the survey of the lochs of Scotland, and whose heroic death while endeavouring to save life in Airthrey Loch last February must be present to the memory of many of you. Large sums of money devoted in good faith to scientific purposes do not always bring about the wished-for result; but in this case there is no room for anxiety on that score. Sir John Murray, with whom Mr. Fred Pullar had worked for several years, has generously promised to direct the whole scheme, and to be responsible for carrying it out. All the lakes of the British Islands will be sounded and mapped as a preliminary to the complete limnological investigation which is proposed. The nature of the deposits, the chemical composition of the water and its dissolved gases, the rainfall of the drainage areas, the volumes of the inflowing and outflowing streams, the fluctuations in the level of the surface, the seasonal changes of temperature, and the nature and distribution of aquatic plants and animals will all receive attention. The geological history of the lakes may also be inquired into with reference to such points as the growth of deltas, the erosion of the margins, and, perhaps, the conditions of the old dead lakes that are now level meadows.

Five years at least will be required to make these observations and to incorporate them in memoirs, each of which will be a complete natural history of the lakes of one river basin. The proposed work wants more than money, direction and time. It requires the services of several young and enthusiastic workers—preferably men who have completed their University course and are anxious to devote some time to research. Sir John Murray and Mr. Pullar wish to meet three or four capable young fellows, one preferably a chemist, one a geologist, one a botanist, and one a zoologist. When found they will be offered a salary sufficient to enable them to give their whole time to the work, but not large enough to induce anyone who has not the love of science at heart to take it up. From my experience when working in somewhat similar conditions at the Scottish Marine Station seventeen years ago, I can promise those who will have the good fortune to be selected plenty of hard work for which they will get the fullest credit—and this they will appreciate more keenly when they come to know the world better—and I can promise them also in their association with Sir John Murray a course of scientific and intellectual training such as even the universities do not afford.

Other Desirable Surveys.

The Geological Map requires to be supplemented by additional work on the nature of the superficial soil as it affects agriculture, such as is expressed in the *Cartes agronomiques* of France, going more fully into the chemical nature of the soil than is possible on the Drift Maps of the Survey which so usefully supplement the maps of solid geology. Such experiments as have been made at the College at Reading in collecting analyses of the soils in the neighbourhood might very well be carried out at the agricultural colleges and other centres all over the country. It would form an invaluable supplement to the work of the Government geologists.

Of equal value, though, perhaps, more obviously so to the scientific than to the "practical" man, is the study of the natural vegetation of the country. In a highly cultivated land like ours there are comparatively few places where the native flora remains in possession, but the mapping of the main crops which have supplanted it is nearly as useful. To become satisfactory from this point of view, the statistics of the Board of Agriculture ought to be supplemented by surveys made by trained botanists on the ground. A valuable beginning has been made under the ever-fertile stimulus of Prof. Patrick Geddes in the two sheets of a map of the plant-associations of Scotland compiled by the late Robert Smith, whose premature death last year was a loss to science. It would be a splendid thing if this map could be finished as a memorial to the brilliant young botanist in the same way as the survey of the lakes is proposed as a memorial worthy of Fred Pullar, and I am glad to learn that there is some probability of it being carried on.

Of all the other distributions which might be worked out cartographically time fails us to speak; but reference must be made, however briefly, to a few.

Geography of the Air.

With regard to Meteorology, the distribution of temperature and pressure over the British Islands for the year and for the separate months have been worked out by the experienced hand of Dr. Buchan and published both in separate memoirs and in the "Meteorological Atlas," edited by Dr. Buchan and Dr. Herbertson. But such observations as the degree of cloud or of sunshine can as yet be treated only in a superficial and generalised way for want of data. Perhaps the most important and certainly the most difficult of all the atmospheric conditions to discuss fully is precipitation. It depends on so many varying conditions, such as the form and exposure of the land, the altitude above sea-level, the direction and force of the wind, the relative frequency of thunderstorms, the distance from the sea, the direction of the average paths of cyclonic storms, &c., that far more numerous and more long-continued observations are required to establish the normal condition of the country than in the case of either temperature or pressure. When we reflect that the whole water-supply of the country depends directly on rainfall, and when we remember that the value of water-power made available by differences of level promises to be greater in the future than it has been in the past, we can see that a study of rainfall in conjunction with configuration may prove as valuable for the localisation of the manufacturing centres of the future as the geological survey was for those of the present.

Thanks to the remarkable foresight and the untiring exertions of the late Mr. Symons, the volunteer rainfall observers of this country have been encouraged to organise their efforts, and by working on a common plan have accumulated within the last forty years a mass of observations unrivalled for number and completeness in any other land. But as yet the difficulties in the way of constructing a map of normal rainfall on an adequate scale have not been overcome, and much experimental work will probably be necessary before it can be accomplished. To this task it is my ambition to devote myself. I may be permitted to state that Scotland is far behind England or Wales in the number of rainfall stations per square mile. Thus there is, roughly, one rain-observing station for every 20 square miles of England, one for every 30 square miles of Wales, but only one for every 67 square miles of Scotland, and one for every 170 square miles of Ireland.

Rainfall observations only tell the amount of available water; the configuration of the stream-beds must be considered in determining water-power. The only country I know where the horse-power of the rivers has been measured and mapped is Finland, but of course individual rivers, such as the Mississippi, Rhine, Seine, and Thames, have been thoroughly studied. Before many decades have passed it will be a necessary element in the surveys of all countries, though at present the available data are few and scattered.

Population Maps.

In considering human geography we come to the most interesting and least occupied field of research. Until Mr. Bosse constructed his beautiful maps of the density of population of Scotland and England we had absolutely no cartographical representation of the true distribution of people over the land. To map population by counties gives a very poor idea of the truth, for in such counties as Yorkshire or Perthshire there are large areas entirely without inhabitants, and small areas where the population is very dense. Mr. Bosse's maps were made on the principle of leaving blank all the land on which there were no dwelling houses, and so obtaining a close approximation to the true density of population of the inhabited area. For Scotland his map shows at once that it is a function of configuration. It shows the densely peopled lowland plain, the less densely peopled coast-strip surrounding the country, and the least densely peopled valleys running inland into the great uninhabited areas. The population map of England, on the other hand, shows an absolutely startling relation to the geological structure, which in turn is closely related to the configuration. We are not astonished to see the centres of densest population coinciding with the Coal Measures, but it is both surprising and instructive to see how the density of population runs parallel to the strike of the Secondary and Tertiary rocks of south-eastern England, a band of the lightest population following each outcrop of chalk and limestone, a band of dense population following each belt of sandstone or clay.

Anthropo-geography teems with fascinating subjects of research. The admirable investigations in the West of Ireland on the physical anthropology of the people might well be extended to the whole country outside the great towns, where all evidence of place of origin and original character is speedily lost. Good work has been done in this way by the Ethnographic Survey promoted by a committee of this Association, and a committee of the Royal Scottish Geographical Society has rendered great aid to the Ordnance Survey in the cognate study of the place-names of Scotland.

The distribution of religion, even in the three typical forms of Anglican, Presbyterian, and Roman Catholic—forms so typical as to be, broadly speaking, national—is most imperfectly known. The objection to a religious census is one which is somewhat difficult of comprehension in Scotland, and too polemic for sober discussion in England. But a few of the problems are worth being worked out by individuals. The curious islands of Roman Catholic continuity in Lancashire, the Hebrides and the Highlands can probably be related simply enough to the configuration of the country and the means of communication as influencing free movement of people at critical periods of history. There are many interesting points as to the geographical distribution of surnames, the relation of characteristic literature or poetry to specific areas, things small in themselves, but capable of exercising very far-reaching influence if systematically worked out.

Geographical Synthesis.

Granted that the subsidiary surveys have been made and the results put in a strictly comparable form, the central problem remains—the synthesis of the complete geography of the country. This can perhaps be solved best by comparing the maps of the various distributions in the proper order, and seeing how far they are related to one another. For the general discussion the Ordnance Map on the scale of one inch to a mile should be used, and each natural region ought properly to be treated by itself, but as a matter of practical convenience it would probably be found best to select either the artificial boundaries of counties or the still more arbitrary lines bounding sheets of the map. Whatever small area is taken as the unit of description, it should be treated in such a way as to seek for and prove or disprove the existence of any control exercised by the form of the land and its geological character on the outcrops of the rocks, the nature of the soil, the course of the rivers, the temperature and movements of the air, the rainfall, the vegetation and agriculture, the distribution of population, the sites of towns, villages, and isolated dwellings, the roads, railways and harbours, the birth-rate and death-rate, and on the progressive changes in all these conditions which are shown in the discussion of the statistics collected annually or decennially. When such unit areas are worked out individually the results can easily be combined and condensed into a geographical description that will be complete, well balanced, and symmetrical. The work is practicable; it requires only time, money, direction and workers to carry it out; but although a specimen memoir, prepared by the authority of the Royal Geographical Society, met with a certain measure of approval, all attempts failed to obtain funds for making the work complete, and the scheme must await a more educated generation before it can be profitably revived in its entirety. But meanwhile this field for geographical study and research lies at the doors of every University where the subject is or may be recognised, and the labours of professors and students might be profitably directed to the completion of such memoirs for the surrounding district, gradually working further and further afield. The idea is no more new than every other "thing under the sun." Such exercises, not so elaborately planned, but the same in essentials, were ordinary subjects for theses in the universities of Sweden and Finland during the eighteenth century. To come nearer home, the local handbooks prepared for successive meetings of the British Association are frequently very fair examples of the geographical description of a district. The essential qualities are rarer in guide-books, but we must not forget one brilliant exception, the poet Wordsworth's "Guide to the English Lakes."

It is pleasant to hear that through the encouragement of Sir John Murray the Scottish Natural History Society is taking up the systematic study of the basin of the Forth, and they will, I feel sure, give a good account of their labours. One point which must be very strongly emphasised is that a geographical treatise is distinguished from a jumble of facts mainly by the order and proportion in which the phenomena are dealt with, and by the relation of cause and effect that is established between them.

As to the utility of complete geographical descriptions, we must of course recognise their greater practical importance in new and developing countries than in old lands like our own. Yet even with us the study of the distribution of natural resources may suggest important changes, involving great redistributions of population.

A Geographical Warning.

Hitherto, except as regards exploration and cartography, the position of geography in this country has never been satisfactory. Times are changing, and even in exploration we are now only one amongst many rivals, often better equipped by education, usually in no way deficient in daring. Although the best work of several of our cartographers in Edinburgh and London need fear no comparison, we cannot conceal the fact that Germany leads the world in map-making. As regards the recognition or even the comprehension of geography by the State, by the universities and by the public, we are equally far behind our neighbours across the North Sea.

It has sometimes been hinted that the study of geography has been deliberately discouraged by politicians or by merchants because too much knowledge on the part of the public might embarrass foreign policy or lead to mercantile competition; but we surely cannot entertain such unworthy suspicions. I am inclined to attribute the neglect of the subject merely to ignorance of its nature due to imperfect education.

Two cases in which the application of geography to political and practical affairs suggests a definite course of action may be mentioned as examples. There is still one important colonial boundary entirely undelimited in a region somewhat difficult of access and still little known, where goldfields will probably be found or reported before long, and where a very serious international question may suddenly arise in a part of the world absolutely unsuspected by most people, even amongst those who interest themselves in general politics and in colonial affairs. It would cost a comparative trifle to survey the region in question, and to lay down that boundary line before the goldfields are touched, so that no international trouble could ever arise. What it may cost to postpone the matter until claims have been pegged out on debatable land, the British Guiana and Venezuela arbitration, the Alaska difficulty, and South Africa are there to tell us. It would be interesting to calculate, now that the cost of a week of fighting is known, the saving in pennies on the income tax that would have accrued from a survey of South Africa if that had been carried out as an imperial duty when Cape Colony was settled. I do not for a moment suggest that a survey would have prevented the war; but it is not unreasonable to believe that it would have shortened it by some months. In this connection it is satisfactory to know that a valuable report has been drawn up by a Committee of the British Association, presided over by Sir Thomas Holdich, embodying a scheme for the systematic survey of British protectorates.

The second example comes nearer home. The utilisation of wind- and water-power must increase in importance as mineral fuel diminishes in amount or increases in price. Wind- and water-power will never fail as long as the sun shines and the land remains higher than the sea; but what may fail unless timely precautions are taken is the power of utilising them for the benefit of the community at large. Are the existing laws as to water-rights, and the absence of laws as to the utilisation of wind desirable and satisfactory? The usual answer to such questions is, "Why trouble about that just now? These matters are not urgent, other things are." That argument is answerable for many disasters. The inevitable is in many if not in most cases simply another name for the unforeseen. It is inevitable that the country will be impoverished if the utilisation of wind- and water-power and the transport of that power by electricity are not wisely safeguarded and provided for; but when a survey of our resources, the circulation of the air over our islands, and the effects produced by the interposition of the mountains, plateaus, and valleys upon it, plainly points to the possibility of such a trouble, it only becomes inevitable as a result of culpable negligence.

These two examples, which will not strike anyone whose mind is wholly occupied in paying the penalties of old neglect, illustrate my contention that a complete geographical description based on full investigation is of the highest and most urgent importance, not for this country only, but for the Empire, and for every country in the world.

Nor is it the land alone which claims attention. It is of the utmost importance to investigate and evaluate the resources of the surrounding seas. The recent International Conference for the exploration of the sea held at Christiania formulated a scheme of research which has been taken up enthusiastically by Belgium, Holland, Germany, Denmark, Russia, Sweden and Norway. Its object is to place the fisheries of Northern Europe on a scientific basis, and to make for that purpose a comprehensive survey of the sea, which will prove of high value to meteorology, and through it to agriculture as well. The recent work by Mr. H. N. Dickson on the circulation of the surface waters of the North Atlantic in conjunction with similar work by Prof. Pettersson in Sweden shows how hopeful such researches are from the purely scientific standpoint, and their practical importance is no less. It remains with our Government to show that this country is not indifferent to an opportunity, such as has never presented itself before, of placing one of our great national industries on a basis of scientific knowledge. This is in my belief one of the cases in which the expenditure of thousands now will mean the saving of millions a few years hence.

It is magnificent to send out polar expeditions, and they speak volumes for the greatness of the human mind that can give itself to the advancement of knowledge for the sake of knowledge, knowing that it will bring no material gain; and I trust that such a spirit will continue to manifest itself until no spot of Earth, no land however cold or hot, no depth of sea, no farthest limit of the atmosphere remains unsearched and its lesson unlearnt. But I insist that the full study of our own country is on a totally different footing. Magnificent it may be, too, but sternly practical, since it is absolutely essential for our future well-being, and even for the continuance of the nation as a Power amongst the States of the world. Still, there is every probability that such work will be neglected until the events which it should avert are upon us, and then it will be too late to make provisions which now could be done cheaply, easily, and effectively.

A Proposed Remedy.

The few attempts which have been made in this country to promote the study of geography or to diminish the discouragements to geographical research have had but slight success. Much has been done to improve geographical teaching by the Royal Geographical Society, the Royal Scottish Geographical Society, the Geographical Association, this Section of the British Association, and other bodies; but that is not my theme. I refer to the little that has been done towards the elaboration of a geographical theory and the elucidation of geographical processes. Amongst the not inconsiderable number of teachers of geography in the Universities and Colleges of Great Britain there is not one man who receives a salary on which he can live in decent comfort so as to devote all his time, or a substantial part of it, to geographical research; and the same is true of every official of all the geographical societies. Not one is paid an income sufficient to enable him to devote the time not occupied by mechanical routine to any other purpose than supplementing his income by outside work—writing text-books, correcting examination papers, perhaps even practising journalism. If by an effort and the sacrifice of some of the comforts considered necessary by most people of the professional classes he devotes a few odd hours now and then to some original research, he finds very few to consider it seriously; some friendly expressions of opinion possibly, but scarcely a reader; and it counts for nothing, save, perhaps, in enhancing the reputation of his country in other lands where scientific work, no matter in what department, is valued in a due degree. All this must be changed before much progress can be made. No doubt a giant of genius would ignore all obstacles and pursue his work regardless of recognition; but such giants are not to be looked for many times in a century. It should be made possible for a man of fair abilities to receive as much opportunity, encouragement, recognition and reward for good work in geography as for good work, let us say, in chemistry or electricity. That is all that can reasonably be asked, and that is what is freely accorded in other countries where the status of the man of science is higher than it is with us. It is here that help may be hoped for from the Scottish Universities in the strength of their new endowments. If a Chair of Geography were instituted with the purpose of promoting research first and teaching afterwards, properly equipped with books, maps, and apparatus, and held on the understanding that no outside work was to be undertaken, something might yet be done to restore our country to the position it held a century and a half ago, when a text-book of geography was published without a thought of sarcasm, containing a frontispiece representing "Britannia instructing Europe, Asia, Africa, and America in the Science of Geography."

SECTION H.

ANTHROPOLOGY.

OPENING ADDRESS BY PROF. D. J. CUNNINGHAM, M.D., D.Sc., LL.D., D.C.L., F.R.S., PRESIDENT OF THE SECTION.

TWENTY-FIVE years have passed since the British Association met in Glasgow. This is a long time to look back upon, and yet the period appears short when measured by the great advance which has taken place in almost all branches of knowledge. Anthropology has shared in the general progress. The discoveries made within its confines may not have been so startling, nor yet have had such a direct influence upon the material welfare of the people, as in the case of other fields of scientific study, but its development has been steady and continuous, and it has grown much in public estimation.

At the Glasgow meeting of the Association in 1876 Anthropology held a subsidiary position. It only ranked as a Department, although it gained a special prominence through having Alfred Russel Wallace as its Chairman. It was not until several years later that it became one of the recognised Sections of the Association, and attained the high dignity of having a letter of the alphabet allotted to it. But quite independently of its official status it has always been a branch of study which has been accorded a large amount of popular favour. The anthropological meetings have, as a rule, been well attended, and the discussions, although perhaps on certain occasions somewhat discursive, have never lacked vigour or animation. Prof. Huxley, who presided over the Anthropological Department at the Dublin meeting in 1878, ascribed the popularity of the subject to the many openings which it affords for wide differences of opinion between the exponents of its numerous branches and to the innate bellicose tendency of man. As the representative of a country in which, according to the same high authority, this tendency is less strongly marked than elsewhere, and of a race which has so frequently and pointedly exhibited its abhorrence of vigorous language, I trust that my presence here as President may not react unfavourably on the interest shown in the work of the Section.

The present occasion might appear to be peculiarly appropriate for my taking stock of our anthropological possessions and summing up the numerous additions to our knowledge of "man and his doings" which have been made during the century which has just passed. Such a task, however, is surrounded with so much difficulty that I shrink from undertaking it. The scope of the subject is enormous, and the studies involved so diverse and so varied that I feel that it is beyond my power to give any comprehensive survey of its development in all its parts. I prefer therefore to confine my remarks to that province of Anthropology within which my own work has been chiefly carried on, and from this to select a subject which has for some years held a prominent place in my thoughts. I refer to the human brain and the part which it has played in the evolution of man.

One of the most striking peculiarities of man when regarded from the structural point of view is the relatively great size of his brain. Although with one or two exceptions the several parts of the brain are all more or less involved in this special development, it is the cerebral hemispheres which exhibit the preponderance in the highest degree. This characteristic of the human brain is rendered all the more significant when we consider that the cerebral hemispheres cannot be looked upon as being primitive parts of the brain. In its earliest condition the brain is composed of three simple primary vesicles, and the cerebral hemispheres appear in a secondary manner in the shape of a pair of lateral offshoots or buds which grow out from the foremost of these primitive brain-vesicles.

The offshoots which form the cerebral hemispheres are found in all vertebrates. Insignificant in size and insignificant in functional value in the more lowly forms, a steady increase in their proportions is manifest as we ascend the scale, until the imposing dimensions, the complex structure, and the marvellous functional potentialities of the human cerebral hemispheres are attained. In their development the cerebral hemispheres of man rapidly outstrip all the other parts of the brain until they ultimately usurp to themselves by far the greater part of the cranial cavity. To the predominant growth of the cerebral hemispheres is due the lofty cranial vault of the human skull; to the different degrees of development and to the different forms which they assume are largely due the variations in cranial outline in different individuals and different races—variations in the determination of which the Craniologist has laboured so assiduously and patiently.

I think that it must be manifest to everyone that the work of the Craniologist, if it is to attain its full degree of usefulness, must be founded upon a proper recognition of the relation which exists between the cranium and the brain, or, in other words, between the envelope and its contents.

The cranium expands according to the demands made upon it by the growing brain. The initiative lies with the brain, and in normal conditions it is questionable if the envelope exercises more than a very subsidiary and limited influence upon the form assumed by the contents. The directions of growth are clearly defined by the sutural lines by which the cranial bones are knit together; but these are so arranged that they admit of the expansion of the cranial box in length, in breadth, and in height, and the freedom of growth in each of these different directions has in all probability been originally determined by the requirements of the several parts of the brain.

The base or floor of the cranium, supporting as it does the brain-stem or the parts which possess the greatest phylogenetic antiquity, and which have not undergone so large a degree of modification in human evolution, presents a greater uniformity of type and a greater constancy of form in different individuals and different races than the cranial vault which covers the more highly specialised and more variable cerebral hemispheres.

To what extent and in what directions modifications in the form of the cranium may be the outcome of restrictions placed on the growth of the brain it is difficult to say. But, broadly speaking, I think we may conclude that the influence which the cranium, under normal circumstances, independently exerts in determining the various head-forms is trifling.

When we speak therefore of brachycephalic or short heads, and dolichocephalic or long heads, we are merely using terms to indicate conditions which result from individual or racial peculiarities of cerebral growth.

The brachycephalic brain is not moulded into form by the brachycephalic skull; the shape of both is the result of the same hereditary influence, and in their growth they exhibit the most perfect harmony with each other.

Craniology has been called the "spoiled child of Anthropology." It is supposed that it has absorbed more attention than it deserves, and has been cultivated with more than its share of care, while other fields of Anthropology capable of yielding rich harvests have been allowed to remain fallow. This criticism conveys a very partial truth. The cranium, as we have seen, is the outward expression of the contained brain, and the brain is the most characteristic organ of man; cranial peculiarities therefore must always and should always claim a leading place in the mind of the Anthropologist; and this is all the more imperative seeing that brains of different races are seldom available for investigation, whilst skulls in the different museums may literally be counted by thousands.

Meantime, however, the Craniologist lies buried beneath a mighty mountain of figures, many of which have little morphological value and possess no true importance in distinguishing the finer differences of racial forms. Let us take as an example the figures upon which the cephalic or length-breadth index of the skull is based. The measurement of the long diameter of the cranium does not give the true length of the cranial cavity. It includes, in addition, the diameter of an air-chamber of very variable dimensions which is placed in front. The measurement combines in itself therefore two factors of very different import, and the result is thereby vitiated to a greater or less extent in different skulls. A recent memoir by Schwalbe[1] affords instructive reading on this matter. One case in point may be given. Measured in the usual way, the Neanderthal skull is placed in the dolichocephalic class; whereas Schwalbe has shown that if the brain-case alone be considered it is found to be on the verge of brachycephaly. Huxley, many years ago, remarked that "until it shall become an opprobrium to an ethnological collection to possess a single skull which is not bisected longitudinally" in order that the true proportions of its different parts may be properly determined we shall have no "safe basis for that ethnological craniology which aspires to give the anatomical characters of the crania of the different races of mankind." It appears to me that the truth of this observation can hardly be disputed, and yet this method of investigation has been adopted by very few Craniologists.

It has become too much the habit to measure and compare crania as if they were separate and distinct entities, and without a due consideration of the evolutionary changes through which both the brain and its bony envelope have passed. Up to the present little or no effort has been made to contrast those parts of the cranial wall or cavity which have been specially modified by the cerebral growth-changes which are peculiar to man. It may be assumed that these changes have not taken place to an equal extent, or indeed followed identically the same lines in all races.

Unfortunately our present knowledge of cerebral growth and the value to be attached to its various manifestations is not so complete as to enable us to follow out to the full extent investigations planned on these lines. But the areas of cerebral cortex to which man owes his intellectual superiority are now roughly mapped out, and the time has come when the effect produced upon the cranial form by the marked extension of these areas in the human brain should be noted and the skulls of different races contrasted from this point of view.

To some this may seem a return to the old doctrine of Phrenology, and to a certain extent it is; but it would be a Phrenology based upon an entirely new foundation and elaborated out of entirely new material.

It is to certain of the growth-changes in the cerebrum which I believe to be specially characteristic of man, and which un-

1 "Studien über Pithecanthropus erectus" (Dubois). *Zeitschrift f. Morph. und Anthrop.*, Band i. Heft 1, 1899.

questionably have had some influence in determining head-forms, that I wish particularly to refer in this Address.

The surface of the human cerebrum is thrown into a series of tortuous folds or convolutions separated by slits or fissures, and both combine to give it an appearance of great complexity. These convolutions were long considered to present no definite arrangement, but to be thrown together in the same meaningless disorder as is exhibited in a dish of macaroni. During the latter half, or rather more, of the century which has just ended it has, however, been shown by the many eminent men who have given their attention to this subject that the pattern which is assumed by the convolutions, while showing many subsidiary differences, not only in different races and different individuals, but also in the two hemispheres of the same person, is yet arranged on a consistent and uniform plan in every human brain, and that any decided deviation from this plan results in an imperfect carrying out of the cerebral function. In unravelling the intricacies of the human convolutionary pattern it was very early found that the simple cerebral surface of the ape's brain in many cases afforded the key to the solution of the problem. More recently the close study of the manner in which the convolutions assume shape during their growth and development has yielded evidence of a still more valuable kind. We now know that the primate cerebrum is not only distinguished from that of all lower mammals by the possession of a distinct occipital lobe, but also by having imprinted on its surface a convolutionary design, which in all but a few fundamental details is different from that of any other order of mammals.

There are few matters of more interest to those anthropologists who make a study of the human skull than the relationship which exists between the cranium and the brain during the period of active growth of both. Up to the time immediately prior to the pushing out of the occipital lobe, or, in other words, the period in cerebral development which is marked by the transition from the quadrupedal type to the primate type of cerebrum, the cranial wall fits like a tight glove on the surface of the enclosed cerebrum. At this stage there would appear to be a growth antagonism between the brain and the cranial envelope which surrounds it. The cranium, it would seem, refuses to expand with a speed sufficient to meet the demands made upon it for the accommodation of the growing brain. In making this statement it is right to add that Hochstetter, in a carefully reasoned memoir, has recently cast doubt upon the reality of the appearances which have led to this conclusion, and at the recent meeting of the Anatomische Gesellschaft, in Bonn, Prof. Gustaf Retzius,[1] one of the numerous observers responsible for the description of the early cerebrum upon which the conclusion is based, showed some inclination to waver in his allegiance to the old doctrine. This is not the time or the place to enter upon a discussion of so technical a kind, but I may be allowed to say that whilst I fully recognise the necessity for further and more extensive investigation into this matter I do not think that Hochstetter has satisfactorily accounted for all the circumstances of the case.

When the occipital lobe assumes shape the relationship of the cranial wall to the enclosed cerebrum undergoes a complete change. The cranium expands so rapidly that very soon a wide interval is left between the surface of the cerebrum and the deep aspect of the cranial envelope within which it lies. This space is occupied by a soft, sodden, spongy meshwork, termed the subarachnoid tissue, and it is into the yielding and pliable bed thus prepared that the convolutions grow. At first the surface of the cerebral hemisphere is smooth, but soon particular areas of the cortex begin to bulge out and foreshadow the future convolutions. These suffer no growth restriction, and they assume the form of round or elongated elevations or eminences which rise above the general surface level of the cerebral hemisphere and break up its uniform contour lines in the same manner that mountain chains protrude from the surface of the globe.

As growth goes on, and as the brain gradually assumes a bulk more nearly in accord with the cavity of the cranium, the space for surface protrusions of this kind becomes more limited. The gyral elevations are now pressed together: they become flattened along their summits, and in course of time they acquire the ordinary convolutionary shapes. While this is going on the valleys or intervals between the primitive surface elevations become narrowed, and ultimately assume the linear slit-like form characteristic of the fissures. These changes occur shortly before birth, but are not fully completed until after the first few months of infancy. The final result of this process is that the convolutions come into intimate relation with the deep aspect of the cranial wall and stamp their imprint upon it.

It is obvious that certain of the later changes which I have endeavoured to portray might be ascribed to a growth antagonism between the brain and the enclosing cranium at this period. In reality, however, it is merely a process by which the one is brought into closer adaptation to the other—a using up, as it were, of superfluous space and a closer packing together of the convolutions—after the period of active cortical growth is past. Nevertheless the convolutionary pattern is profoundly affected by it, and it seems likely that in this process we find the explanation of the different directions taken by the cerebral furrows in brachycephalic and dolichocephalic heads.

The cortical elevations which rise on the surface of the early cerebrum are due to exuberant growth in localised areas. There cannot be a doubt that the process is intimately connected with the development of function in the districts concerned. We know that functions of different kinds are localised in different parts of the cortex, and when we see an area on the surface of the early cerebrum rise up in the form of an eminence we may reasonably conclude that the growth in the area concerned is the structural foundation of what will become later on a centre of functional activity of an acute kind.

A consideration of this matter gives the clue to the simple convolutions of the ape and the complex convolutions of man, and, further, it explains how the interrupted form of fissural development is one of the essential characteristics of the human brain as compared with the simian brain. Areas which rise up in the form of one long elevation on the surface of the ape's brain appear in the form of several eminences on the surface of the human brain, and fissures which appear in the form of long continuous slits in the simian cerebrum appear in the human cerebrum in several detached bits, which may or may not in the course of time run into each other and become confluent. All this is due to the greater definition, refinement, and perfection of the functions carried on in the cerebral cortex of man. It is an index of a more complete "physiological division of labour" in the human brain.

It is not necessary, for the purpose I have in view, to enter into any detail regarding the many points of difference which become evident when the cerebral surface of the ape is compared with that of man. It is more my purpose to indicate certain of the districts of cerebral cortex which have undergone a marked increase in the human brain—an increase which may be reasonably supposed to be associated with the high mental attributes of man. To us, at the present time, it is difficult to conceive how it was ever possible to doubt that the occipital lobe is a distinctive character of the simian brain as well as of the human brain, and yet at successive meetings of this Association (1860, 1861, and 1862) a discussion, which was probably one of the most heated in the whole course of its history, took place on this very point. One of our greatest authorities on animal structure maintained that the occipital lobe and the hippocampus minor—an elevation in its interior—were both peculiar to man and to him alone. Everyone has read in the "Water Babies" Charles Kingsley's delightful account of this discussion. Speaking of the Professor he says: "He held very strange theories about a good many things. He had even got up at the British Association and declared that apes had hippopotamus majors in their brains just as men have. What a shocking thing to say; for if it were so, what would become of the faith, hope and charity of immortal millions? You may think that there are other more important differences between you and an ape, such as being able to speak, and make machines, and know right from wrong, and say your prayers, and other little matters of that kind; but that is a child's fancy." In the light of our present knowledge we can fully understand Prof. Huxley closing the discussion by stating that the question had "become one of personal veracity." Indeed, the occipital lobe, so far from being absent, is developed in the ape to a relatively greater extent than in man, and this constitutes one of the leading positive distinctive characters of the simian cerebrum. Measured along the mesial border, the percentage length of the occipital lobe to the total length of the cerebrum in the baboon, orang, and man is as follows:—

Baboon	29·7
Orang	23·2
Man	21·2

[1] Anatomische Gesellschaft. Bonn, May 21, 1901. Gustaf Retzius, "Transitorische Furchen des Grosshirns."

But these figures do not convey the full extent of the predominance of the occipital lobe in the ape. The anterior border of the lobe grows forwards beyond its proper limits, and pushes its way over the parietal lobe which lies in front, so as to cover over a portion of it by an overlapping lip termed the occipital operculum. There is not a trace of such an arrangement in the human brain, and even in the anthropoid ape the operculum has become greatly reduced. Indeed, in man there is exactly the reverse condition. The great size of the parietal lobe is a leading human character, and it has partly gained its predominance by pushing backwards so as to encroach, to some extent, upon the territory which formerly belonged to the occipital lobe.[1] A great authority[2] on the cerebral surface refers to this as a struggle between the two lobes for surface extension of their respective domains. "In the lower apes," he says, "the occipital lobe proves the victor: it bulges over the parietal lobe as far as the first annectant gyrus. Already, in the orang, the occipital operculum has suffered a great reduction; and in man the victory is on the side of the parietal lobe which presses on the occipital lobe and begins, on its part, to overlap it." Now that so much information is available in regard to the localisation of function in the cerebral cortex, and Flechsig has stimulated our curiosity in regard to his great "association areas" in which the higher intellectual powers of man are believed to reside, it is interesting to speculate upon the causes which have led to the pushing back of the scientific frontier between the occipital and parietal cerebral districts.

The parietal lobe is divided into an upper and a lower part by a fissure, which takes an oblique course across it. Rudinger,[3] who studied the position and inclination of this fissure, came to the conclusion that it presents easily determined differences in accordance with sex, race and the intellectual capacity of the individual. He had the opportunity of studying the brains of quite a number of distinguished men, amongst whom were Bischoff of Bonn, Döllinger of Munich, Tiedemann of Heidelberg, and Liebig of Munich, and he asserts that the higher the mental endowment of an individual the greater is the relative extent of the upper part of the parietal lobe.

There is absolutely no foundation for this sweeping assertion. When the evolutionary development of the parietal part of the cerebral cortex is studied exactly the reverse condition becomes manifest. It is the lower part of the parietal lobe which in man, both in its early development and in its after growth, exhibits the greatest relative increase. Additional interest is attached to this observation by the fact that recently several independent observers have fixed upon this region as one in which they believe that a marked exuberance of cortical growth may be noted in people of undoubted genius. Thus Retzius has stated that such was the case in the brains of the astronomer Hugo Gyldén,[4] and the mathematician Sophie Kovalevsky;[5] Hansemann[6] has described a similar condition in the brain of Helmholtz; and Guszman[7] in the brain of Rudolph Lenz, the musician. Some force is likewise added to this view by Flechsig, who, in a recent paper,[8] has called attention to the fact that within this district there are located two of his so-called "Terminalgebiete," or cortical areas, which attain their functional powers at a later period than those which lie around them, and which may therefore be supposed to have specially high work to perform.

Without in any way desiring to throw doubt upon the observations of these authorities, I think that at the present moment it would be rash to accept, without further evidence, conclusions which have been drawn from the examination of the few brains of eminent men that have been described. There cannot be a doubt that the region in question is one which has extended greatly in the human brain, but the association of high intellect with a special development of the region is a matter on which I must confess I am at present somewhat sceptical.

But it is not only in a backward direction that the parietal lobe in man has extended its territory. It has likewise increased in a downward direction. There are few points more striking than this in the evolution of the cerebral cortex of man. In order that I may be able to make clear the manner in which this increase has been brought about, it will be necessary for me to enter into some detail in connection with the development of a region of cerebral surface termed the *insular district*. The back part of the frontal lobe is also involved in this downward extension of surface area, and, such being the case, it may be as well to state that the boundary which has been fixed upon as giving the line of separation between the parietal and frontal districts is purely artificial and arbitrary. It is a demarcation which has no morphological significance, whilst from a physiological point of view it is distinctly misleading.

The insular district in the fœtal brain is a depressed area of an elongated triangular form. The general surface of the cerebrum occupies, all round about it, a more elevated plane, and thus the insula comes to be bounded by distinct walls, like the sides of a shallow pit dug out in the ground. The upper wall is formed by the lower margins of the frontal and parietal lobes, the lower wall by the upper margin of the temporal lobe, and the front wall by the frontal lobe. From each of these bounding walls a separate portion of cerebral cortex grows, and these gradually creep over the surface of the insula so as to overlap it, and eventually completely cover it over and exclude it from the surface, in the same way that the lips overlap the teeth and gums. That which grows from above is called the *fronto-parietal operculum*, while that which grows from below is termed the *temporal operculum*. These appear very early, and are responsible for closing over more than the hinder three-fourths of the insula. The lower or temporal operculum is in the first instance more rapid in its growth than the upper or fronto-parietal operculum, and thus it comes about that when their margins meet more of the insula is covered by the former than by the latter. So far the development is apparently precisely similar to what occurs in the ape. The slit or fissure formed by the approximation of the margins of these two opercula is called the Sylvian fissure, and it constitutes a natural lower boundary for the parietal and frontal lobes which lie above it. At first, from the more energetic growth of the lower temporal operculum, this fissure slants very obliquely upwards and backwards, and is very similar in direction to the corresponding fissure in the brain of the ape. But in the human brain this condition is only temporary. Now begins that downward movement of the parietal lobe and back part of the frontal lobe to which reference has been made. The upper or fronto-parietal operculum, in the later stages of fœtal life and the earlier months of infancy, enters into a growth antagonism with the lower or temporal operculum, and in this it proves the victor. The margins of the two opercula are tightly pressed together, and, slowly but surely, the fronto-parietal operculum gains ground, pressing down the temporal operculum, and thus extending the territory of the frontal and parietal districts. This is a striking process in the brain development of man, and it results in a depression of the Sylvian fissure or the lower frontier line of the frontal and parietal lobes. Further, to judge from the oblique direction of the Sylvian fissure in the brain of the ape, the process is peculiar to man; in the simian brain there is no corresponding increase in the area of cerebral cortex under consideration.

I do not think that it is difficult to account for this important expansion of the cerebral surface. In the fore part of the region involved are placed the groups of motor centres which control the muscular movements of the more important parts of the body. These occupy a broad strip of the surface which stretches across the whole depth of the district concerned. Within this are the centres for the arm and hand, for the face, the mouth and the throat, and likewise, to some extent, the centre for speech. In man certain of these have undoubtedly undergone marked expansion. The skilled movements of the hands, as shown in the use of tools, in writing, and so on, have not been acquired without an increase in the brain mechanism by which these are guided. So important, indeed, is the part played by the human hand as an agent of the mind, and so perfectly is it adjusted with reference to this office, that there are many who think that the first great start which man obtained on the path

[1] It is necessary to emphasise this point, because in Wiedersheim's "Structure of Man" we are told that in man there is a preponderance of the occipital lobe, and that the parietal lobe is equally developed in man and anthropoids.

which has led to his higher development was given by the setting of the upper limb free from the duty of acting as an organ of support and locomotion. It is an old saying "that man is the wisest of animals because of his hands." Without endorsing to its full extent this view, I think that it cannot be a matter for surprise that the district of the cerebral cortex in man in which the arm-centres reside shows a manifest increase in its extent.

In the same region of cerebral cortex, but at a lower level, there are also situated the centres which are responsible for facial expression. In the ape there is a considerable degree of facial play; but this is chiefly confined to the region of the lips; and the muscles of the face, although present in greater mass, show comparatively little of the differentiation which is characteristic of the lighter and more feeble muscles in the face of man. And then as to the effect produced: These human muscles are capable of reflecting every fleeting emotion, every change of mind, and by the lines and furrows their constant use indelibly fix on the countenance the character and disposition of an individual can to some extent be read. As the power of communication between primitive men became gradually established, facial movements were no doubt largely used, not only for the purpose of giving expression to simple emotions, such as anger or joy, but also for giving point and force to the faltering speech of our early progenitors by reflecting other conditions of mind. The acquisition of this power as well as the higher and more varied powers of vocalisation must necessarily have been accompanied by an increase of cerebral cortex in the region under consideration. And in this connection it is a point well worthy of note that the area of cortex mapped out in the human brain[1] as controlling the muscles of the face, mouth, and throat is as large, if not larger than that allotted to the arm and hand,[2] and yet it is questionable if all the muscles under the sway of the former would weigh as much as one of the larger muscles (say the triceps) of the arm. This is sufficient to show that it is not muscle power which determines the extent of the motor areas in the cerebral cortex. It is the degree of refinement in the movements required, as well as the degree of variety in muscle combinations, which apparently determines the amount of ground covered by a motor centre.

Still, the increase in the amount of cerebral cortex in man due to the greater refinement of movement acquired by different groups of muscles is relatively small in comparison with the increase which has occurred in other regions from which no motor fibres are sent out, and which therefore have no direct connection with muscles.

The remarkable conclusions arrived at by Flechsig, although not confirmed and accepted in all their details, have tended greatly to clear up much that was obscure in the relations of the different districts of cerebral cortex. More particularly has he been able to apportion out more accurately the different values to be attached to the several areas of the cerebral surface. He has shown that fully two thirds of the cortex in the human brain constitute what he terms "association centres." Within these the higher intellectual manifestations of the brain have their origin, and judgment and memory have their seat. They are therefore to be regarded as the psychic centres of the cerebral cortex.

Now, it requires a very slight acquaintance with the cerebral surface to perceive that the great and leading peculiarity of the human brain is the wide extent of these higher association centres of Flechsig. Except in connection with new faculties, such as speech, there has been relatively no striking increase in the extent of the motor areas in man as compared with the cortex of the ape or the idiot, but the expansion of the association areas is enormous and the increase in the frontal region and the back part of the parietal region is particularly well marked. It is this parietal extension of surface which is chiefly responsible for the pushing down of the lower frontier of the parietal lobe and the consequent enlargement of its territory.

I have already referred to the views which have been recently urged by several independent observers, that in the men who have been distinguished during life by the possession of exceptional intellectual power, this region has shown a very special development.

It is a curious circumstance, and one which is worthy of consideration, that in the left cerebral hemisphere the Sylvian fissure or the lower boundary of the parietal lobe is more depressed than in the right hemisphere, and, as a result of this, the surface area occupied by the parietal lobe is greater on the left side of the brain than on the right side. To the physiologist it is a matter of every-day knowledge that the left cerebral hemisphere shows in certain directions a marked functional preeminence. Through it the movements of the right arm and right side of the body are controlled and regulated. Within it is situated also the active speech centre. This does not imply that there is no speech centre on the right side, but simply that the left cerebral hemisphere has usurped the chief, if not the entire, control of this all-important function, and that from it are sent out the chief part, if not the whole, of the motor incitations which give rise to speech. The significance attached to the dominant power of the left hemisphere receives force from the now well-established fact that in left-handed individuals the speech function is also transferred over to the right side of the brain. To account for this functional preeminence of the left cerebral hemisphere numerous theories have been elaborated. The interest attached to the subject is very considerable, but it is impossible on the present occasion to do more than indicate in the briefest manner the three views which have apparently had the widest influence in shaping opinion on this question. They are: (1) that the superiority of the left cerebral hemisphere is due to its greater weight and bulk; (2) that it may be accounted for by the greater complexity of the convolutions on the left brain and the fact that these make their appearance earlier on the left side than on the right side; (3) that the explanation lies in the fact that the left side of the brain enjoys greater advantages in regard to its blood supply than the right side.

Not one of these theories when closely looked into is found to possess the smallest degree of value. Braune[1] has shown in the most conclusive manner that if there is any difference in weight between the two hemispheres it is a difference in favour of the right and not of the left hemisphere; and I may add from my own observations that this is evident at all periods of growth and development. Equally untrustworthy are the views that have been put forward as to the superiority of the left hemisphere from the point of view of convolutionary development. I am aware that it is stated that in two or three cases where the brains of left-handed people have been examined this superiority was evident on the right hemisphere. This may have been so; I can only speak for the large percentage of those who are right-handed; and I have never been able to satisfy myself that either in the growing or fully developed brain is there any constant or marked superiority in this respect of the one side over the other; and I can corroborate Ecker (*Archiv für Anthropologie*, 1868, Bd. cxi.) in his statement that there is no proof that the convolutions appear earlier on the one side than the other. The theory that an explanation is to be found in a more generous blood supply to the left hemisphere is more difficult to combat, because the amount of blood received by each side of the brain depends upon two factors, viz., the physical conditions under which the blood-stream is delivered to the two hemispheres and the calibre of the arteries or tubes of supply. Both of these conditions have been stated to be favourable to the left hemisphere. It is a matter of common anatomical knowledge that the supply pipes to the two sides of the brain are laid down somewhat differently, and that the angles of junction, &c., with the main pipe are not quite the same. Further, it is true that the blood-drains which lead away the blood from the brain are somewhat different on the two sides. Whether this would entail any marked difference in the blood-pressure on the two sides I am not prepared to say. This could only be proved experimentally; but, taking all the conditions into consideration, I am not inclined to attach much importance to the argument It is easy to deal with the loose statements which have been made in regard to the size of leading supply pipe (viz., the internal carotid artery). It passes through a bony canal in the floor of the cranium on its way into the interior of the cranial box. Its size can therefore be accurately gauged by measuring the sectional area of this bony tunnel on each side.

1 See diagram in Schäfer's article on the "Cerebral Cortex" in his recent work on physiology.

2 The comparison only refers to surface area, and this is not an absolutely true criterion of the relative amount of cortex in each region. The arm-centre has a large amount of cortex stowed away within the fissure of Rolando in the shape of inter-locking gyri which is not taken into account in a measurement confined to the superficial surface area. Still, this does not to any great degree detract from the argument which follows, seeing that the discrepancy is still sufficiently marked.

1 "Das Gewichtsverhältniss der rechten zur linken Hirnhälfte beim Menschen" (*Archiv für Anat.*).

This I have done in twenty-three skulls chosen at random, and the result shows that considerable differences in this respect are to be found in different skulls. These discrepancies, however, are sometimes in favour of the one side and at other times in favour of the other side; and when the combined sectional area for all the skulls examined was calculated it was, curiously enough, found to be 583⅓ sq. mm. for the left side and 583 sq. mm. for the right side.

Leaving out of count the asymmetry in the arrangement of the convolutions in the two hemispheres, which cannot by any amount of ingenuity be twisted into such a form as to give a structural superiority to one side more than the other, the only marked difference which appears to possess any degree of constancy is the increase in the territory of the left parietal lobe produced by the more marked depression of its lower frontier line (Sylvian fissure). That this is in any way associated with right-handedness or with the localisation of the active speech centre in the left hemisphere I am not prepared to urge, because the same condition is present in the ape. It is true that some authorities[1] hold that the ape is right-handed as well as man, but in the gardens of the Royal Zoological Society of Ireland I have had a long and intimate experience of both anthropoid and lower apes, and I have never been able to satisfy myself that they show any decided preference for the use of one arm more than the other.

That differences do exist in the more intimate structural details of the two hemispheres, which give to the left its functional superiority, there cannot be a doubt; but these have still to be discovered. Bastian has stated that the grey cortex on the left side has a higher specific gravity, but this statement has not as yet received corroboration at the hands of other observers.

I have already mentioned that man's special endowment, the faculty of speech, is associated with striking changes in that part of the celebral surface in which the motor centre for articulate speech is located. It is questionable whether the acquisition of any other system of associated muscular movements has been accompanied by a more evident cortical change. The centre in question is placed in the lower and back part of the frontal lobe. We have seen that the insular district is covered over in the hinder three-fourths of its extent by the fronto-parietal and temporal opercula, and thus submerged below the surface and hidden from view. The brain of the ape and also of the microcephalic idiot with defective speech goes no further in its development. The front part of the insular district remains uncovered and exposed to view on the surface of the cerebrum. In man, however, two additional opercula grow out and ultimately cover over the fore part of the insula. These opercula belong to the lower and back part of the frontal lobe, and are to be looked upon as being more or less directly called into evidence in connection with the acquisition of articulate speech.

The active speech centre is placed in the left cerebral hemisphere. We speak from the left side of the brain, and yet when the corresponding region[2] on the right side is examined it is found to go through the same developmental steps.

The stimulus which must have been given to general cerebral growth in the association areas by the gradual acquisition of speech can hardly be exaggerated.

During the whole course of his evolution there is no possession which man has contrived to acquire which has exercised a stronger influence on his higher development than the power of articulate speech. This priceless gift, "the most human manifestation of humanity"—(Huxley)—was not obtained through the exertions of any one individual or group of individuals. It is the result of a slow process of natural growth, and there is no race, no matter how low, savage or uncultured, which does not possess the power of communicating its ideas by means of speech. "If in the present state of the world," says Charma, "some philosopher were to wonder how man ever began to build those houses, palaces and vessels which we see around us, we should answer that these were not the things that man began with. The savage who first tied the branches of shrubs to make himself a shelter was not an architect, and he who first floated on the trunk of a tree was not the creator of navigation." And so it is with speech. Rude and imperfect in its beginnings, it has gradually been elaborated by the successive generations that have practised it.

The manner in which the faculty of speech originally assumed shape in the early progenitors of man has been much discussed by Philologists and Psychologists, and there is little agreement on the subject. It is obvious that all the more intelligent animals share with man the power of giving expression to certain of the simpler conditions of mind both by vocal sounds and by bodily gestures. These vocal sounds are of the interjectional order, and are expressive of emotions or sensations. Thus the dog is said, as a result of its domestication, to have acquired the power of emitting four or five different tones, each indicative of a special mental condition and each fully understood by its companions. The common barn-door fowl has also been credited with from nine to twelve distinct vocal sounds, each of which is capable of a special interpretation by its fellows or its chickens. The gestures employed by the lower animals may in certain cases be facial, as expressed by the grimaces of a monkey, or changes in bodily attitude, as we see continually in the dog.

I think that it may not be unreasonably inferred that in the distant past the remote progenitors of man relied upon equally lowly means of communicating with their fellows, and that it was from such humble beginnings that speech has been slowly evolved.

There cannot be a doubt that this method of communicating by vocal sounds, facial expression and bodily gestures is capable of much elaboration; and, further, it is possible, as some hold, that it may have attained a considerable degree of perfection before articulate speech began to take form and gradually replace it. Much of it indeed remains with us to the present day. A shrug of the shoulders may be more eloquent than the most carefully prepared phrase; an appropriate expression of face, accompanied by a suitable ejaculation, may be more withering than a flood of invective. Captain Burton tells us of a tribe of North American Indians whose vocabulary is so scanty that they can hardly carry on a conversation in the dark. This and other facts have led Mr. Tylor, to whom we owe so much in connection with the early history of man, to remark: "The array of evidence in favour of the existence of tribes whose language is incomplete without the help of gesture-signs, even for things of ordinary import, is very remarkable"; and, further, "that this constitutes a telling argument in favour of the theory that gesture-language is the original utterance of mankind out of which speech has developed itself more or less fully among different tribes." It is a significant fact also, as the same author points out, that gesture-language is, to a large extent, the same all the world over.

Many of the words employed in early speech were undoubtedly formed, in the first instance, through the tendency of man to imitate the natural sounds he heard around him. To these sounds, with various modifications, was assigned a special conventional value, and they were then added to the growing vocabulary. By this means a very decided forward step was taken, and now primitive man became capable of giving utterance to his perceptions by imitative sounds.

Max Müller, although bitterly opposed to the line of thought adopted by the "Imitative School" of philologists, has expressed their views so well that I am tempted to use the words he employed in explaining what he satirically branded as the "Bow-wow Theory." He says: "It is supposed that man, being yet mute, heard the voices of the birds, dogs, and cows, the roaring of the sea, the rustling of the forest, the murmur of the brook, and the whisper of the breeze. He tried to imitate these sounds, and finding his mimicking cries useful as signs of the object from which they proceeded, he followed up the idea and elaborated language."

Hood[1] humorously and unconsciously illustrates this doctrine by a verse descriptive of an Englishman, ignorant of French, endeavouring to obtain a meal in France:—

"'Moo!' I cried for milk;
If I wanted bread
My jaws I set agoing;
And asked for new-laid eggs
By clapping hands and crowing."

[1] Ogle, "On Dextral Preeminence," *Trans.* Med. Chirurg. Soc., 1871; Aimé Père, "Les Courbures latérales normales au rachis humain." (Toulouse, 1900.)

[2] Rudinger and others have tried on very unsubstantial grounds to prove that there is a difference in this region on the two sides of the brain. There is, of course, as a rule, marked asymmetry; but I do not think that it can be said with truth that the cortical development of the region is greater on the left side than on the right.

[1] Quoted from "The Origin of Language," by Hensleigh Wedgwood, 1866.

But, although much of early articulate speech may have arisen by the development of interjectional sounds and the reproduction, by the human vocal organs, of natural sounds, it is very unlikely that these afforded the only sources from which words were originally derived. Romanes insists upon this, and, in support of his argument, refers to cases where children invent a language in which apparently imitative sounds take no part. He likewise alludes to the well-known fact that deaf mutes occasionally devise definite sounds which stand for the names of friends. In the light of such evidence, he very properly asks, "Why should it be held impossible for primitive man to have done the same?"

The value of spoken language, as an instrument of thought, is universally admitted, and it is a matter incapable of contradiction that the higher intellectual efforts of man would be absolutely impossible were it not for the support which is afforded by articulate speech. Darwin expresses this well when he says: "A complex train of thought can no more be carried on without the aid of words, whether spoken or silent, than a long calculation without the use of figures or symbols." Such being the case, I think we may conclude that the acquisition of speech has been a dominant factor in determining the high development of the human brain. Speech and mental activity go hand in hand. The one has reacted on the other. The mental effort required for the coining of a new word has been immediately followed by an increased possibility of further intellectual achievement through the additional range given to the mental powers by the enlarged vocabulary. The two processes, mutually supporting each other and leading to progress in the two directions, have unquestionably yielded the chief stimulus to brain development.

More than one Philologist has insisted that "language begins where interjection ends." For my part I would say that the first word uttered expressive of an external object marked a new era in the history of our early progenitors. At this point the simian or brute-like stage in their developmental career came to an end and the human dynasty endowed with all its intellectual possibilities began. This is no new thought. Romanes clearly states that in the absence of articulation he considers it improbable that man would have made much psychological advance upon the anthropoid ape, and in another place he remarks that "a man-like creature became human by the power of speech."

The period in the evolution of man at which this important step was taken is a vexed question and one in the solution of which we have little solid ground to go upon beyond the material changes produced in the brain and the consideration of the time that these might reasonably be supposed to take in their development.

Darwin was inclined to believe that articulate speech came at an early period in the history of the stem-form of man. Romanes gives a realistic picture of an individual decidedly superior to the anthropoid ape, but distinctly below the existing savages. This hypothetical form, half-simian, half-human, was, according to his sponsor, probably erect; he had arrived at the power of shaping flints as tools, and was a great adept at communicating with his fellows by gesture, vocal tones, and facial grimaces.

With this accomplished ancestor in his mental eye it is not surprising that Romanes was inclined to consider that articulate speech may have come at a later period than is generally supposed.

At the time that Romanes gave expression to these views he was not acquainted with the very marked structural peculiarities which distinguish the human brain in the region of the speech centre. I do not refer to the development of the brain in other districts, because possibly Romanes might have held that the numerous accomplishments of his speechless ancestor might be sufficient to account for this; I merely allude to changes which may reasonably be held to have taken place in direct connection with the gradual acquisition of speech.

These structural characters constitute one of the leading peculiarities of the human cerebral cortex, and are totally absent in the brain of the anthropoid ape and of the speechless microcephalic idiot.

Further, it is significant that in certain anthropoid brains a slight advance in the same direction may occasionally be faintly traced, whilst in certain human brains a distinct backward step is sometimes noticeable. The path which has led to this special development is thus in some measure delineated.

It is certain that these structural additions to the human brain are no recent acquisition by the stem-form of man, but are the result of a slow evolutionary growth—a growth which has been stimulated by the laborious efforts of countless generations to arrive at the perfect coordination of all the muscular factors which are called into play in the production of articulate speech.

Assuming that the acquisition of speech has afforded the chief stimulus to the general development of the brain, and thereby giving it a rank high above any other factor which has operated in the evolution of man, it would be wrong to lose sight of the fact that the first step in this upward movement must have been taken by the brain itself. Some cerebral variation—probably trifling and insignificant at the start, and yet pregnant with the most far-reaching possibilities—has in the stem-form of man contributed that condition which has rendered speech possible. This variation, strengthened and fostered by natural selection, has in the end led to the great double result of a large brain with wide and extensive association areas and articulate speech, the two results being brought about by the mutual reaction of the one process upon the other.

SECTION I.

PHYSIOLOGY.

OPENING ADDRESS BY PROF. JOHN G. MCKENDRICK, M.D., LL.D., F.R.S., PRESIDENT OF THE SECTION.

WHEN the British Association met in Glasgow twenty-five years ago I had the honour of presiding over Physiology, which was then only a sub-section of Section D. The progress of the science during the quarter of a century has been such as to entitle it to the dignity of a Section of its own, and I feel it to be a great honour to be again put in charge of the subject. While twenty-five years form a considerable portion of the life of a man, from some points of view they constitute only a short period in the life of a science. But just as the growth of an organism does not always proceed at the same rate, so is it with the growth of a science. There are times when the application of new methods or the promulgation of a new theory causes rapid development, and there are other times when progress seems to be slow. But even in these quiet periods there may be steady progress in the accumulation of facts, and in the critical survey of old questions from newer points of view. So far as physiology is concerned, the last quarter of a century has been singularly fruitful, not merely in the gathering in of accurate data by scientific methods of research, but in the way of getting a deeper insight into many of the problems of life. Thus our knowledge of the phenomena of muscular contraction, of the changes in the secreting cell, of the interdependence of organs illustrated by what we now speak of as internal secretion, of the events that occur in the fecundated ovum and in the actively growing cell, of the remarkable processes connected with the activity of an electrical organ, and of the physiological anatomy of the central nervous organs, is very different from what it was twenty-five years ago. Our knowledge is now more accurate, it goes deeper into the subject, and it has more of the character of scientific truth. For a long period the generalisations of physiology were so vague, and apparently so much of the nature of more or less happy guesses, that our brethren the physicists and chemists scarcely admitted the subject into the circle of the sciences. Even now we are sometimes reproached with our inability to give a complete solution of physiological problem, such as, for example, what happens in a muscle when it contracts; and not long ago physiologists were taunted by the remark that the average duration of a physiological theory was about three years. But this view of the matter can only be entertained by those who know very little about the science. They do not form a just conception of the difficulties that surround all physiological investigation, difficulties far transcending those relating to research in dead matter; nor do they recollect that many of the more common phenomena of dead matter are still inadequately explained. What, for example, is the real nature of elasticity; what occurs in dissolving a little sugar or common salt in water; what is electrical conductivity? In no domain of science, except in mathematics, is our knowledge absolute; and physiology shares with the other sciences the possession of problems that, if I may use a paradox, seem to be more insoluble the nearer we approach their solution.

The body of one of the higher animals—say that of man—is a highly complex mechanism, consisting of systems of organs, of individual organs, and of tissues. Physiologists have been able to give an explanation of the more obvious phenomena. Thus locomotion, the circulation of the blood, respiration, digestion, the mechanism of the senses, and the general phenomena of the nervous system have all been investigated, and in a general way they are understood. The same statement may be made as to the majority of individual organs. It is when we come to the phenomena in the living tissues that we find ourselves in difficulties. The changes happening in any living cell, let it be a connective tissue corpuscle, or a secreting cell, or a nerve-cell, are still imperfectly understood; and yet it is upon these changes that the phenomena of life depend. This has led the more thoughtful physiologists in recent years back again to the study of the cell and of the simple tissues that are formed from cells. Further, it is now recognised that if we are to give an adequate explanation of the phenomena of life, we should study these, not in the body of one of the lower organisms, as was at one time the fashion, where there is little if any differentiation of function—the whole body of an amœboid organism showing capacities for locomotion, respiration, digestion, &c.—but in the specialised tissue of one of the higher animals. Thus the muscle-cell is specialised for contraction, and varieties of epithelium have highly specialised functions.

But when cells are examined with the highest microscopic powers, and with the aid of the highly elaborated methods of modern histology, we do not seem to have advanced very far towards an explanation of the ultimate phenomena. There is the same feeling in the mind of the physiologist when he attacks the cell from the chemical side. By using large numbers of cellular elements, or by the more modern and fruitful methods of micro-chemistry, he resolves the cell-substance into proteids, carbohydrates, fats, saline matter and water, with possibly other substances derived from the chemical changes happening in the cell while it was alive; but he obtains little information as to how these proximate constituents, as they are called, are built up into the living substance of the cell. But if we consider the matter it will be evident that the phenomena of life depend on changes occurring in the interactions of particles of matter far too small even to be seen by the microscope. The physicist and the chemist have not been content with the investigation of large masses of dead matter, but to explain many phenomena they have had recourse to the conceptions of molecules and atoms and of the dynamical laws that regulate their movements. Thus the conception of a gas as consisting of molecules having a to-and-fro motion, first advanced by Krönig in 1856 and by Clausius in 1857, has enabled physicists to explain in a satisfactory manner the general phenomena of gases, such as pressure, viscosity, diffusion, &c. In physiology few attempts have been made in this direction, probably because it was felt that data had not been collected in sufficient numbers and with sufficient accuracy to warrant any hypothesis of the molecular structure of living matter, and physiologists have been content with the microscopic and chemical examination of cells, of protoplasm, and of the simpler tissues formed from cells. An exception to this general remark is the well-known hypothesis of Du Bois-Reymond as to the existence in muscle of molecules having certain electrical properties, by which he endeavoured to explain the more obvious electrical phenomena of muscle and nerve. The conception of gemmules by Darwin and of biophors by Weismann are examples also of a hypothetical method of discussing certain vital phenomena.

The conception, however, of the existence in living matter of molecules has not escaped some astute physicists. The subject is discussed with his usual suggestiveness by Clerk Maxwell in the article Atom in the "Encyclopædia Britannica" in the volume published in 1875, and he places before the physiologist a curious dilemma. After referring to estimates of the diameter of a molecule made by Loschmidt in 1865, by Stoney in 1868, and by Lord Kelvin (then Sir W. Thomson) in 1870, Clerk Maxwell writes:—

"The diameter and the mass of a molecule, as estimated by these methods, are, of course, very small, but by no means infinitely so. About two millions of molecules of hydrogen in a row would occupy a millimetre, and about two hundred million million million of them would weigh a milligramme. These numbers must be considered as exceedingly rough guesses; they must be corrected by more extensive and accurate experiments as science advances; but the main result, which appears to be well established, is that the determination of the mass of a molecule is a legitimate object of scientific research, and that this mass is by no means immeasurably small.

"Loschmidt illustrates these molecular measurements by a comparison with the smallest magnitudes visible by means of a microscope. Nobert, he tells us, can draw 4000 lines in the breadth of a millimetre. The intervals between these lines can be observed with a good microscope. A cube, whose side is the 4000th of a millimetre, may be taken as the *minimum visible* for observers of the present day. Such a cube would contain from 60 to 100 million molecules of oxygen or of nitrogen; but since the molecules of organised substances contain on an average about fifty of the more elementary atoms, we may assume that the smallest organised particle visible under the microscope contains about two million molecules of organic matter. At least half of every living organism consists of water, so that the smallest living being visible under the microscope does not contain more than about a million organic molecules. Some exceedingly simple organism may be supposed built up of not more than a million similar molecules. It is impossible, however, to conceive so small a number sufficient to form a being furnished with a whole system of specialised organs.

"Thus molecular science sets us face to face with physiological theories. It forbids the physiologist from imagining that structural details of infinitely small dimensions can furnish an explanation of the infinite variety which exists in the properties and functions of the most minute organisms.

"A microscopic germ is, we know, capable of development into a highly organised animal. Another germ, equally microscopic, becomes when developed an animal of a totally different kind. Do all the differences, infinite in number, which distinguish the one animal from the other arise each from some difference in the structure of the respective germs? Even if we admit this as possible, we shall be called upon by the advocates of pangenesis to admit still greater marvels. For the microscopic germ, according to this theory, is no mere individual but a representative body, containing members collected from every rank of the long-drawn ramification of the ancestral tree, the number of these members being amply sufficient not only to furnish the hereditary characteristics of every organ of the body and every habit of the animal from birth to death, but also to afford a stock of latent gemmules to be passed on in an inactive state from germ to germ, till at last the ancestral peculiarity which it represents is revived in some remote descendant.

"Some of the exponents of this theory of heredity have attempted to elude the difficulty of placing a whole world of wonders within a body so small and so devoid of visible structure as a germ by using the phrase structureless germs. Now one material system can differ from another only in the configuration and motion which it has at a given instant. To explain differences of function and development of a germ without assuming differences of structure is, therefore, to admit that the properties of a germ are not those of a purely material system."

The dilemma thus put by Clerk Maxwell is (first) that the germ cannot be structureless, otherwise it could not develop into a future being, with its thousands of characteristics; or (second) if it is structural it is too small to contain a sufficient number of molecules to account for all the characteristics that are transmitted. A third alternative might be suggested, namely, that the germ is not a purely material system, an alternative that is tantamount to abandoning all attempts to solve the problem by the methods of science.

It is interesting to inquire how far the argument of Clerk Maxwell holds good in the light of the knowledge we now possess. First, as regards the *minimum visible*. The smallest particle of matter that can now be seen with the powerful objectives and compensating eyepieces of the present day is between the $\frac{1}{400000}$th and the $\frac{1}{500000}$th of a inch, or $\frac{1}{20000}$th of a millimetre in diameter, that is to say, five times smaller than the estimate of Helmholtz of $\frac{1}{4000}$th of a millimetre. The diffraction of light in the microscope forbids the possibility of seeing still smaller objects, and when we are informed by the physicists that the thickness of an atom or molecule of the substances investigated is not much less than a millionth of a millimetre, we see how far short the limits of visibility fall of the ultimate structure of matter.

Suppose, then, we can see with the highest powers of the microscope a minute particle having a diameter of $\frac{1}{20000}$th of a millimetre, it is possible to conceive that some of the phenomena of vitality may be exhibited by a body even of such small dimensions. The spores of some of the minute objects now studied by the bacteriologist are probably of this minute size, and it is possible that some may be so minute that they can never be seen. It has been observed that certain fluids derived from the culture of micro-organisms may be filtered through thick asbestos filters, so that no particles are seen with the highest powers, and yet those fluids have properties that cannot be explained by supposing that they contain toxic substances in solution, but rather by the assumption that they contain a greater or less number of organic particles so small as to be microscopically invisible. I am of opinion, therefore, that it is quite justifiable to assume that vitality may be associated with such small particles, and that we have by no means reached what may be called the vital unit when we examine either the most minute cell or even the smallest particle of protoplasm that can be seen. This supposition may ultimately be of service in the framing of a theory of vital action.

Weismann in his ingenious speculations has imagined such a vital unit to which he gives the name of a biophor, and he has even attempted numerical estimates. Before giving his figures let us look at the matter in another way. Take the average diameter of a molecule as the millionth of a millimetre, and the smallest particle visible as the $\frac{1}{20000}$th of a millimetre. Imagine this small particle to be in the form of a cube. Then there would be in the side of the cube, in a row, fifty such molecules, or in the cube $50 \times 50 \times 50 = 125{,}000$ molecules. But a molecule of organised matter contains about fifty elementary atoms. So that the 125,000 molecules in groups of about fifty would number $\frac{125000}{50} = 2500$ organic particles. Suppose, as was done by Clerk Maxwell, one half to be water; there would remain 1250 organic particles. The smallest particle that can be seen by the microscope may thus contain as many as 1250 molecules of such a substance as a proteid.

Weismann's estimates as to the dimensions of the vital unit to which he gives the name of biophor may be shortly stated. He takes the diameter of a molecule at $\frac{1}{20000000}$th of a millimetre (instead of the one millionth) and he assumes that the biophor contains 1000 molecules. Suppose the biophor to be cubical, it would contain ten in a row, or $10 \times 10 \times 10 = 1000$. Then the diameter of the biophor would be the sum of ten molecules, or $\frac{1}{20000000} \times 10 = \frac{10}{20000000}$ or $\frac{1}{2000000}$th of a millimetre. Two hundred biophors would therefore measure $\frac{200}{2000000}$ or $\frac{1}{1000}$ mm. or 1 μ (micron $= \frac{1}{1000}$th mm.). Thus a cube one side of which was 1 μ would contain $200 \times 200 \times 200 = 8{,}000{,}000$ biophors. A human red blood corpuscle measures about 7·7 μ; suppose it to be cubed, it would contain as many as 3,652,264,000 biophors.

Now if the smallest particle that can be seen ($\frac{1}{20000}$th mm.) may contain 1250 molecules, let us consider how many exist in a biophor, which we may imagine as a little cube, each side of which is $\frac{1}{2000000}$th mm. There would then be five in a row of such molecules, or in the cube $5 \times 5 \times 5 = 125$ molecules; and if the half consisted of water about sixty molecules.

Let us apply these figures to the minute particles of matter connected with the hereditary transmission of qualities. The diameter of the germinal vesicle of the ovum is $\frac{1}{20}$th of a millimetre. Imagine this a little cube. Taking the diameter of an atom at $\frac{1}{10000000}$th of a millimetre, and assuming that about fifty exist in each organic molecule (proteid, &c.), the cube would contain at least 25,000,000,000,000 organic molecules. Again, the head of the spermatozoid, which is all that is needed for the fecundation of an ovum, has a diameter of about $\frac{1}{200}$ mm. Imagine it to be cubed; it would then contain 25,000,000,000 organic molecules. When the two are fused together, as in fecundation, the ovum starts on its life with over 25,000,000,000,000 organic molecules. If we assume that one half consists of water, then we may say that the fecundated ovum may contain as many as about 12,000,000,000,000 organic molecules. Clerk Maxwell's argument that there were too few organic molecules in an ovum to account for the transmission of hereditary peculiarities does not apparently hold good. Instead of the number of organic molecules in the germinal vesicle of an ovum numbering something like a million, the fecundated ovum probably contains millions of millions. Thus the imagination can conceive of complicated arrangements of these molecules suitable for the development of all the parts of a highly complicated organism, and a sufficient number, in my opinion, to satisfy all the demands of a theory of heredity. Such a thing as a structureless germ cannot exist. Each germ must contain peculiarities of structure sufficient to account for the evolution of the new being, and the germ must therefore be considered as a material system.

Further, the conception of the physicist is that molecules are more or less in a state of movement, and the most advanced thinkers are striving towards a kinetic theory of molecules and of atoms of solid matter which will be as fruitful as the kinetic theory of gases. The ultimate elements of bodies are not freely movable each by itself; the elements are bound together by mutual forces, so that atoms are combined to form molecules. Thus there may be two kinds of motion, atomic and molecular. By molecular motion is meant "the translatory motion of the centroid of the atoms that form the molecule, while as atomic motion we count all the motions which the atoms can individually execute without breaking up the molecule. Atomic motion includes, therefore, not only the oscillations that take place within the molecule, but also the rotation of the atoms about the centroid of the molecule." [1]

Thus it is conceivable that vital activities may also be determined by the *kind* of motion that takes place in the molecules of what we speak of as living matter. It may be different in kind from some of the motions known to physicists, and it is conceivable that life may be the transmission to dead matter, the molecules of which have already a special kind of motion, of a form of motion *sui generis*.

I offer these remarks with much diffidence, and I am well aware that much that I have said may be regarded as purely speculative. They may, however, stimulate thought, and if they do so they will have served a good purpose, although they may afterwards be assigned to the dust-heap of effete speculations. Meyer writes as follows in the introduction to his great work on "The Kinetic Theory of Gases," p. 4:—"It would, however, be a considerable restriction of investigation to follow out only those laws of nature which have a general application and are free from hypothesis; for mathematical physics has won most of its successes in the opposite way, namely, by starting from an unproved and unprovable, but probable, hypothesis, analytically following out its consequences in every direction, and determining its value by comparison of these conclusions with the result of experiment."

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

SIR PHILIP MAGNUS will distribute the prizes to students of the Morley Memorial College, Waterloo Road, on October 1.

THE Report of the Board of Education, reviewing the proceedings of the Board for the year which ended with last year, has been published as a Blue-book. Reference is made to the Committee appointed to consider the best means of coordinating the technological work of the Board with that at present carried on by other educational organisations. The report of the Committee was received some time ago, and is now "under consideration." It is to be hoped that the report will soon be issued and action taken upon it.

SCIENTIFIC SERIALS.

The American Journal of Science, September.—The discharge current from a surface of large curvature, by John E. Almy. It was found that the current discharging from a fine wire to a concentric cylinder is given by the equation

$$I = LaV(V - b)/r^3,$$

where I is the discharge current, V is the potential difference between the wire and cylinder, L is the length of the discharge wire, r the radius of the cylinder, b the minimum potential necessary to produce a measurable discharge, and a a constant depending upon the size of the wire, the nature of the discharging gas and the sign of the discharge.—On octahedrite and brookite from Brindletown, North Carolina, by H. H. Robinson.—On the behaviour of small closed cylinders in organ pipes, by B. Davis. When small gelatine capsules or light paper cylinders were placed in a stopped organ pipe, on sounding the pipe the cylinders immediately moved to the middle of the stationary loop and arranged themselves in rows across the pipe. The effects produced were of the same nature as the Kundt dust figures.—On a cæsium-tellurium fluoride, by H. L. Wells and

[1] Meyer, "Kinetic Theory of Gases." Translated by Baynes, London, 1899, p. 6.

J. M. Willis. Only one double fluoride could be obtained of the formula $CsF.TeF_4$.—On the double chlorides of cæsium and thorium, by H. L. Wells and J. M. Willis.—Studies of Eocene mammalia in the Marsh collection, Peabody Museum, by J. L. Wortman.—On the separation of the least volatile gases of atmospheric air and their spectra, by G. D. Liveing and J. Dewar (from the *Proceedings* of the Royal Society).—The estimation of calcium, strontium and barium as their oxalates, by C. A. Peters. In the estimation of calcium by titration of the oxalate with permanganate accurate results may be obtained when hydrochloric acid (with a manganous salt) is used as a solvent. The conditions have also been worked out under which barium and strontium can be accurately estimated as oxalates.—On calaverite, by S. L. Penfield and W. E. Ford.

Transactions of the American Mathematical Society, July.—On the convergence of continued fractions with complex elements, by E. B. Van Vleck. Few theorems of a general character have hitherto been obtained, and these but of recent date. The present paper recapitulates these, and some new criteria are deduced. The demonstrations are based upon certain equations which the writer believes to be new and of a fundamental character. The references to previous memoirs form a useful feature.—Geometry within a linear spherical complex, by P. F. Smith, is a paper devoted to the study of a point-sphere correspondence of involutory character, which appears as a direct generalisation from a certain point of view of the well-known point-sphere correspondence arising in a dilatation and the point-point correspondence of spherical inversion. Illustrative problems are discussed.—A new determination of the primitive continuous groups in two variables, by H. F. Blichfeldt. These groups can, by a proper choice of the variables, be transformed into *projective groups* of the plane, a result which Lie obtains after determining the canonical forms of the primitive groups. This fact can, however, be established from the general properties of such groups, and its use leads to a new determination which it is the object of the paper to show.—Determination of all the groups of order p^m which contain the Abelian group of type $(m-2,1)$, p being any prime, by G. A. Miller.—On a fundamental property of a minimum in the calculus of variations, and the proof of a theorem of Weierstrass's, by W. F. Osgood.—Concerning Harnack's theory of improper definite integrals, by E. H. Moore. The paper considers the improper simple definite integrals of Harnack (1883, 1884), and opens with a capital introduction to the bibliography of the subject.—Zur linearen transformation der ϑ-reihen, by F. Mertens.—All the papers were presented at different meetings of the American Mathematical Society, ranging from October 1900 to July 1901.

SOCIETIES AND ACADEMIES.

NEW SOUTH WALES.

Linnean Society, July 31.—Mr. J. H. Maiden, president, in the chair.—Further notes on supposed hybridisation among the Eucalypts: with the description of a new species, by Henry Deane and J. H. Maiden.—Notes on the botany of the interior of New South Wales, part iv., by R. H. Cambage. The country particularly referred to comprises the district between Mount Hope and Parkes, the route traversed generally following the very low range which forms the watershed between the Lachlan and the Bogan Rivers. Mallees were found to be numerous near Mount Hope, but had ceased before Parkes was reached. *Eucalyptus conica*, Deane and Maiden, and *E. albens* were met with near Trundle.—Contributions to a knowledge of Australian Entozoa, part i., description of a new species of *Distomum* from the Platypus, by S. J. Johnston. *Distomum ornithorhynchi*, n.sp., is found in the stomach, duodenum and proximal portion of the small intestine of the duckbill. The species falls into Dujardin's subgenus *Brachylaimus*.—Revised census of the marine mollusca of Tasmania, by Prof. Ralph Tate and W. L. May. By far the greater number of the named species of Tasmania have been known by description only, covered by the papers of Tenison-Woods, 1875–81, and continued by Petterd and Beddome to 1884; and in consequence many of the species have been re-described under different names. The efforts of the authors, carried on for many years, are to bring these little known species into relationship with the constituents of neighbouring local faunas. The authors have had access to very nearly all of the local types, and their knowledge of the Australian fauna imparts to their interpretation of the Tasmanian species a value which may be accepted as correct in the main. The unfigured species, including about 30 new forms, number 120 or thereabouts, which are illustrated. Two new genera are established, *Petterdella*, based on *Stylifer Tasmanica*, T.-Wds., which has the general form and aperture of *Rissoina* and the heterostrophe nucleus of *Eulimella*; and *Thraciopsis* (nomen mutandum) = *Alicia*, Angas *non* Johnston (1861). A new species of a previously unknown genus in Australia, *Cyamium*, is described. Among some of the several changes in generic location is the transference of *Cominella tenuicostata* to *Phos* in a sectional group belonging to the Older Tertiaries of Australia. This is not the only instance of the survival of an Eocene genus in an unique species in the waters of Southern Australia and Tasmania. The number of species in the census of Tenison-Woods has been considerably reduced, but many extralimital species have been added. The total number is 676, grouped as follows:—Cephalopoda, 10; Gastropoda, 503; Scaphopoda, 4; Lamellibranchiata, 156: Palliobranchiata, 3.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part 1 for 1901, contains the following memoirs communicated to the Society:—

January 12.—W. Voigt: on the pyromagnetism and piezomagnetism of crystals.

February 23.—W. Boy: on the representation of the projective plane on a finite closed surface free from singularities.

March 9.—E. Zermelo: on the addition of transfinite cardinal numbers. H. Liebmann: on the flexure of the closed ring-surface. W. Nernst and E. H. Riesenfeld: on electrolytic phenomena at the common surface of two solvents. W. Kaufmann: on an analogy between the behaviour of Nernst's "incandescent oxides" and that of conducting gases.

May 11.—Emil Cohn: on the equations of the electromagnetic field for bodies in motion.

The *Minutes* of the Society contain brief reports on the progress of the Mathematical Encyclopædia, and of the new edition of Gauss's works, together with an obituary notice of Prof. Max Müller.

CONTENTS.

THURSDAY, OCTOBER 3, 1901.

A SCIENTIFIC ENGINEER.

Papers on Mechanical and Physical Subjects. By Prof. Osborne Reynolds, F.R.S. Vol. ii. 1881–1900. Pp. xii+740. (London: C. J. Clay and Sons, 1901.) Price 21*s*. net.

A FULL account of the first volume of Prof. Osborne Reynolds' collected papers has already appeared in these pages (vol. lxii. p. 243). The second volume, which is no less interesting than its predecessor, brings the author's contributions to mechanical science up to date and enables us to realise the value of the work he has done. The twenty-seven papers here printed vary, no doubt, in importance; but throughout them all Prof. Reynolds has kept one aim clearly in view, the application of physical and mechanical principles to engineering problems; whether he is dealing, as in the first paper, with the question of the fundamental limits of speed or, as in the last, with the reasons why ice is slippery, this aim is always before the author.

It is difficult from a volume of this kind to make a selection of points to notice; there are, however, three papers which stand out conspicuously as dealing in a luminous manner with three fundamental problems. The first is No. 44, an experimental investigation of the circumstances which determine whether the motion of water shall be direct or sinuous, and of the law of resistance in parallel channels. The second, No. 52, on the theory of lubrication and its application to Mr. Beauchamp Tower's experiments, and the third, No. 66, on the method, appliances and limits of error in the direct determination of the work expended in raising the temperature of ice-cold water to that of water boiling under a pressure of 29·899 inches of ice-cold mercury in Manchester. A few lines may be given to each of these in turn.

The fact that for narrow tubes and for small velocities the resistance to the flow of water in a tube is proportional to the velocity follows from the experiments of Poiseuille and others. It was also known that this law did not hold in larger tubes or when the velocity was considerably increased, but the cause of the change and the relation of the velocity to the radius for which it occurred in a given tube were unknown until the date of Prof. Reynolds' experiments. He showed that if D be the diameter of the tube, V the velocity of the stream and P the ratio of the coefficient of viscosity to the density, then the change of resistance takes place at a velocity V given by the equation $V = P/BD$ when B is a constant, and, moreover, that at this critical velocity the motion of the water in the tube changes from direct to sinuous; eddies and vortices are set up which are intimately connected with the change in resistance. Further experiments showed that up to the critical velocity the slope of pressure in the tube varies as the velocity, while for velocities considerably greater than the critical the slope of pressure varies as the velocity raised to the power of 1·72.

The second paper deals with Mr. Tower's experiments on lubrication. Mr. Tower had shown that when the rubbing surfaces, the friction between which was being investigated, were totally immersed in oil, a thin film of oil was formed between them, within which the pressure was enormously greater than in the oil bath; in some cases it was as much as 625 lbs. to the square inch above the pressure in the bath.

Prof. Reynolds gives a very complete account of the existence of this film and of the conditions for complete and incomplete lubrication.

In the last paper mentioned the author gives the theory of a very valuable redetermination of Joule's equivalent.

The laboratory at the Owens College is fitted with a set of triple expansion engines which can be arranged to work on three special hydraulic brake dynamometers, the energy being absorbed by a stream of water which passes through the brake. This water can be taken from a tank holding some 60 tons in a tower 116 feet above the laboratory floor.

The experiment, put briefly, consisted in measuring the work put into the brake, the temperature of the incoming and outflowing water and the quantity of that water. Prof. Reynolds' paper contains a detailed exposition of the theory, with an account of the precautions taken and calculations required to allow for the various sources of error.

The experiments were conducted by Mr. Moorby, and are very closely concordant. It results from them that the mean specific heat of water between freezing and boiling points is 776·94 ft. lbs., or in C.G.S. units 41832000 ergs.

Other papers of great interest and importance might easily be mentioned; for these we must refer the reader to the book itself, at the same time congratulating the author on the conclusion of the task he was asked to undertake and the Cambridge University Press on the service it is rendering to science by its series of reprints of mathematical and physical papers.

NORTH AMERICAN INSECTS.

The Insect Book: a Popular Account of the Bees, Wasps, Ants, Grasshoppers, Flies, and other North American Insects, exclusive of the Butterflies, Moths, and Beetles, with full Life-histories, Tables and Bibliographies. By Leland O. Howard, Ph.D., Chief of the Division of Entomology, U.S. Department of Agriculture. Pp. xxvii+429; 47 plates (plain and coloured), and 264 woodcuts. (New York: Doubleday, Page and Co., 1901.) Price 3 dollars net = 12*s*.

IN the preface to Dr. Holland's admirable "Butterfly Book," the author mentioned that he might subsequently issue a similar work on the moths. The book before us is uniform with Dr. Holland's, who is, as Dr. Howard informs us in his preface, engaged on the promised volume of moths, while another volume on the beetles is in contemplation, we presume by, or under the supervision of, Dr. Howard, though this is not explicitly stated.

Enormous strides have been made in the study of North American entomology during the last forty years, and there must now be a very considerable number of entomologists in the country. No doubt many of these devote themselves to the popular orders of Lepidoptera and Coleoptera, as in Europe; but nevertheless there are numerous active workers, known or unknown, in all the so-called "neglected orders," and a popular manual on these insects, freely illustrated, must greatly conduce to their more extended study, though it is, of course, impossible to treat of five great orders of insects in a single volume in anything like so complete a manner as Dr. Holland was able to achieve for the limited group of butterflies. Dr. Howard has, however, contrived to bring together and condense a large amount of very useful information from various sources, and his book should prove nearly as valuable to European as to North American entomologists; for not only are a large proportion of the various families and genera common to both countries, but a considerable number even of the species here described and figured are common and well-known British species. Here and there we find a slip, as when the number of described species of Hymenoptera is estimated on the first page as nearly 30,000, whereas it almost certainly exceeds 40,000 at the present time; and at p. 345 the exploded superstition originated by Kirby and Spence that earwigs do *not* enter the human ear seems to be insisted on. Perhaps the rarity of earwigs in the States may partly account for this.

We have already said that some of the species included in this work are common British species. Others are large and handsome forms quite unlike any existing in England, or perhaps in Europe. This is especially the case in the orders Orthoptera and Neuroptera; and the pretty plates of dragonflies, especially plates 40 and 43, representing species with coloured wings, will be something like a revelation to the entomologist familiar only with the hundred European species of dragonflies, not more than three or four of which have any considerable amount of colour in the wings, though this is partly atoned for by the bright colours of their bodies.

Most, if not all, of the figures in the plates are probably original; but most of the text illustrations are copied from Riley, Packard, Comstock and other well-known writers.

As is usual with recent American writers, Dr. Howard admits several more families of insects than the seven with which most of our English entomologists are satisfied. Tables of families are given in several of the orders, which will greatly facilitate the work of a beginner. Otherwise, however, there is little technical matter in the book, which mainly consists of descriptions of habits and transformations. There is a good deal of light readable matter; and Mr. Marlatt's account of the way in which boys in Kansas rob humble-bees' nests by enticing the bees into a jar half filled with water will be equally new and amusing to most English readers.

Turning to the end of the volume, we find a good but not too extensive index of thirteen pages, double columns, preceded by a bibliography of twelve pages, very closely printed in double columns, and arranged systematically in a manner that seems a little puzzling till one gets used to it. This will prove a most useful part of the book to serious workers, and it brings out very forcibly the enormous periodical literature to which Dr. Howard alludes in his preface and which is so conspicuous a eature of the American entomological literature of the present day. The bibliography is preceded by a section on "Collecting and Preserving Insects," freely illustrated in the text, like the rest of the book, which, although primarily written for American entomologists, may also furnish useful hints to European collectors.

We cannot do less than strongly recommend Dr. Howard's book to all entomologists who are interested in theorders of insects to which it refers, repeating that the main features of the book are the detailed life-histories and the number of good illustrations of the insects discussed.

OUR BOOK SHELF.

Nature Teaching. By Francis Watts, F.I.C., F.C.S. Pp. 199. (London: Dulau and Co. Barbados: Bowen and Sons.)

THIS is a very useful volume, issued under the authority of the Imperial Commissioner of Agriculture for the West Indies. It is based upon the general principles of agriculture, and has been designed for the use of schools in the islands. Although these colonies depend entirely on the proper cultivation of the soil, there has hitherto been practically no attempt made to impart to the rising generation a knowledge of even the elements of agriculture. Like everything else in the mother country and in Britain across the seas, the rule of thumb, happy-go-lucky system has been preferred to scientific methods, with the result that we are all being left behind in the race. The Imperial Commissioner notes that one of the most hopeful features connected with the West Indies is the general movement which is now taking place in favour of agricultural teaching. Teachers in charge of schools have during the past three years been undergoing training sufficient to enable them to impart a fair knowledge of botanical principles to their scholars, and the volume now prepared by Mr. Watts, with the assistance of Mr. Maxwell-Lefroy, is intended to guide the teachers in the way they should go. The work is divided into nine chapters, dealing respectively with the seed, the root, the stem, the leaf, the soil, plant food and manures, flowers and fruits, weeds, and insects. Simple language is used in describing each subject, and every chapter ends with copious instructions on practical work. Thus the chapter on the seed deals with the parts of a seed; plant food in seeds; and germination; while under "practical work" we find described the conditions for germination; raising seedlings; seed beds; observations on seedlings; and testing vitality of seeds. A glossary and appendices are added. The book is not intended as an ordinary reading-book, but for the use of the older pupils who have already received oral instruction in the various subjects.

Cassell's Eyes and No Eyes Series. Book I. *Wild Life in Woods and Fields.* Pp. 48. Book II. *By Pond and River.* Pp. 48. Book III. *Plant Life in Field and Garden.* Pp. 80. Book IV. *Birds of the Air.* Pp. 79. By Arabella B. Buckley (Mrs. Fisher). (London: Cassell and Co., 1901.) Price, Books I. and II., 4*d.* each; Books III. and IV., 6*d.* each.

THESE attractive little books will promote an intelligent interest in plants and animals among the children who read them. In very simple words Mrs. Fisher describes some insects, birds, flowers, and other living things familiar to observers of outdoor nature, and her descriptions will doubtless direct the attention of many pupils to natural history studies. Each book has several nicely coloured plates in addition to numerous other illustrations. In rural schools the books should be of exceptional value.

LETTER TO THE EDITOR.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Long-tailed Japanese Fowls.

WITH reference to my previous letter on this subject, I should like to draw the attention of the readers of NATURE to a very interesting paper in the *Transactions* of the Asiatic Society of Japan (vol. xxvii. 1900). The writer, Mr. Basil Hall Chamberlain, who has obtained his information from a Japanese fancier, Mr. Kitagawa Ushimatsu, and has also examined the birds himself, states that "there is absolutely no artificial method of making the feathers grow. All is done by selection. Any failure to obtain good results must proceed from having a bad hen, that is, one not of the true breed, and it is in this point that buyers are liable to be deceived. Also one must know how to treat the birds."

The long tail-feathers, Mr. Chamberlain states, grow during the whole life of the bird, which may extend to eight or nine years. If accidentally pulled out they are reproduced. The rate of growth is about four inches a month in young birds, but as much as seven inches in older specimens. The custom of tying up the tail is stated to be a mistaken one, and not to be followed where the birds are bred. The very best specimens are, not unnaturally, kept at home by the breeders in the Tosa province.

The breed is believed to be about a century old, but its origin is unknown. But it seems obvious from the evidence given that it was bred from birds which "sported" in the direction of continuously-growing feathers, as I suggested. Mr. Chamberlain's paper is illustrated by two excellent photographs of cocks of this breed, one of which at least is evidently far superior to the specimens exhibited at South Kensington, remarkable as these are.

FRANK FINN.

c/o Zoological Society, 3, Hanover-square.

PROF. A. F. W. SCHIMPER.

WILHELM ANDRÉ SCHIMPER, who passed away on September 9 in his forty-sixth year, was the great son of an eminent father. Inheriting from his father, the professor of botany, and from the Abyssinian traveller Schimper, a famous name, he made that name yet more famous.

Schimper studied at the University initially, I believe, with the intention of becoming a mineralogist; and his first paper, on proteid crystals (1879), bears the impress of his special training. But this paper, as well as an early one (issued 1880) on a parasitic flowering plant, *Prosopanche*, has been overshadowed by his later achievements.

It was not until the appearance of his paper on the origin of starch (1880) that the botanical world became aware that a young botanist of power and originality had joined it. Before the appearance of this paper the view prevailed that starch-grains were manufactured either by chlorophyll grains or by the general protoplasm. Schimper showed that starch-grains are invariably produced in specialised masses of protoplasm, in chlorophyll grains, or in colourless "starch-builders." Continuing his researches (1880–1885), he, together with Schmitz, proved that chloroplasts, exclusively by division, arise from preexisting ones (or their homologues), but never by a formation *de novo* from the general protoplasm. Schimper further demonstrated the homology of the three classes of chromatophores—leucoplasts (without colouring matter), chloroplasts (with chlorophyll), and chromoplasts (with red or yellow colouring matter). In fact, while other histologists were showing that the plant-cell and animal-cell had two distinct and individualised kinds of protoplasm—cytoplasm and nucleus—Schimper was demonstrating that a third existed, which, like the other two, could produce, and only be produced by, its like. In other words all (or at least nearly all) indubitable animals possess in their cells only two completely distinct kinds of protoplasm, whereas all indubitable plants, with the exception of fungi, and possibly some of the lowest vegetable organisms, have three kinds; and it is to the possession of this third kind of protoplasm—chromatophore-protoplasm—that the plant world largely owes its evolution.

But Schimper's investigations on starch-grains incidentally aided in the inception of another, though minor, revolution in botanical thought. When Schimper commenced his work on the origin of starch, Naegeli's theory of growth of the cell-wall by intussusception was firmly held. Schimper's observations and considerations on the growth of starch grains, and some of Schmitz's observations, were the first blows struck at Naegeli's theory, in favour of growth by apposition, and doubtless they stimulated Strasburger to furnish his masterly case in support of the latter view.

Not to adopt strict chronological order, but to follow Schimper's researches so far as they dealt with pure physiology or histology, the next paper, on the conduction of carbohydrates (1885), was of value, as an exhibition of a strict physiological method, and as an appeal against the alluring and facile method of endeavouring to solve physiological problems solely by histological observations, rather than as a paper containing essentially new physiological views. Schimper's two succeeding physiological papers, on the formation of calcium oxalate in leaves (1887), and the assimilation of mineral salts (1890), were of greater importance. They introduced the method of following by microchemical tests the various inorganic elements in their course from the root to the leaves. Apart from serving as admirable and novel models of physiological research, these papers proved that the leaves are no mere workshops for the manufacture of carbohydrates, but that they are in reality perfectly equipped factories in which the rawest food materials can be, and are, worked up into elaborate proteid compounds, and even into protoplasm. Schimper further showed that chlorophyll, in addition to affecting the decomposition of carbon dioxide and the production of carbohydrates, also in some way influences the reduction of inorganic salts and the production of proteids, apparently in a direct manner.

Despite the value of his contributions to our knowledge of the histology and physiology particularly of green cells, Schimper's fame is possibly wider as the founder of a true method of investigating the "politics," "biology," "bionomics," or œcology of plants.

Though Sprengel, Darwin, H. Müller and others had set so excellent an example in their treatment of questions relating to the pollination of flowers, in other departments of the subject the œcology of plants was mainly a motley array of ill-considered hypotheses, vain phantasies and unfounded conclusions, and by serious botanists the subject was derided as the "romance of botany." Schimper inaugurated a new era. In dealing with problems on the relation between plants and their environments, he insisted that the same thoroughness and precision should be exercised as in investigating morphological and physiological questions.

Schimper's first œcological paper, on epiphytes (1884), was a veritable revelation, magic as a fairy-story in interest, but severely reasoned in substance. In this, and in its final version (1891), it was shown that epiphytes were children of the moist forests, and had arisen as beings that had won a victory in the struggle for light by seizing positions of vantage with very little expenditure of material. Commencing as humble occupants of the soil within the shady forest, epiphytes had in the course of ages laboriously clambered up the trees, striving after the light, and ever struggling against the precarious and fluctuating supplies of moisture and of humus, inventing new absorbing and fixing organs, and contriving fresh devices for resisting threatened death from thirst or starvation, until at length their perilous career was crowned with success and they formed aërial meadows, gardens, shrubberies, and even forests. Schimper showed that the evolution of epiphytes was still reflected in the forest, where the simplest epiphytes lurk low down in moist shaded crevices of the tree trunks, and the more elaborate ones are ranged successively upwards until, even before the tree-tops are reached, perfection is practically attained. Further, he taught how, having emerged into the full blaze of the tropical sun, some epiphytes had sprung across to the savannahs, where they colonised the isolated trees or clothed the nakedness of the bare rocks. And still later he carried the history one step further and revealed some epiphytes flying up to the mountain-tops and others leaping down to the ground near the sea.

The next œcological paper, that on myrmecophilous plants (1888), furnished relatively little that was new, but by the application of a strict method of research it definitely proved views that had been promulgated by that sagacious naturalist, Belt.

The very brief communication on the means of protection against transpiration (1890) was possibly the most suggestive ever issued by Schimper. In it he explained that terrestrial plants living on or near the sea shore, even in saline swamps, or growing inland in the vicinity of salt springs, require to protect themselves against excessive transpiration owing to the difficulty in obtaining a sufficient supply of water with or without salt. Further, he pointed out that Alpine plants in the tropics, at spots where there is no snow, reveal the same xerophilous character as in temperate regions, and it is against desiccation due to exalted transpiration, and not against cold as such, that Alpine plants have to battle. Finally he directed attention to the fact that in temperate regions deciduous trees shed their leaves because they cannot absorb water sufficiently rapidly from the cold soil; whereas evergreen trees can retain their foliage because of the xerophytic structure of the latter. (Though he was not aware of the fact, Schimper was not the actual discoverer of this truth, for I find that Hales appreciated it.) These considerations led to the solution of several geographical problems. They explained how, in temperate and tropical regions alike, Alpine plants may reappear on the sea shore; how, in the tropics, epiphytes reappear as terrestrial plants on Alpine heights, on the sea shore, or near salt-springs. These plants can interchange positions because they are all adapted to resist one danger—excessive transpiration.

In his last œcological paper on a special subject—the Indo-Malayan littoral vegetation (1891)—the principles enunciated in the preceding work were proved and expanded, and other relations between littoral plants and their animate and inanimate surroundings were dealt with. It is impossible to do justice to this paper in a brief note, but it may be mentioned that the important distinction between salt-loving and salt-hating plants was shown to refer, not merely to plants growing on the shores or inland respectively, but to whole orders or cohorts. Littoral plants, then, are salt-enduring representatives that have been driven by competition to the fringe of vegetation, where they have evolved new features in their vegetative and reproductive parts in order that they may exist and spread abroad from shore to shore.

Schimper's last book, a general work on geographical distribution of plants considered from a physiological standpoint, is beyond doubt one of the most illuminating botanical works ever published. No one save a wide traveller, inspired with a deep love for, and close sympathy with, Nature could have written this masterpiece. It was the crowning piece of his life, for Schimper was stricken down in the midst of a new work on island floras.

In conclusion we may say that Schimper revolutionised our ideas as to the fundamental constitution of the unit of plant life, widened and deepened our knowledge of the physiology of green assimilating cells, and, himself in every field in which he worked an earnest advocate, and even inventor, of strict methods of research, he, in particular, took a foremost place in raising up a true science of œcology. Through the passing of Schimper the world of science is darker by the extinction of a light which, if it did not glow with steady incandescence, yet quivered and scintillated with genius.

PERCY GROOM.

NOTES.

INTRODUCTORY addresses were delivered on Tuesday at several of the London and provincial medical schools, to open the new session. Dr. P. W. Latham, speaking at St. George's Hospital, pointed out that organic chemistry will in time tell exactly what is the composition and constitution of toxins, albumoses, antitoxins, &c., which have proved of service to medicine, and how they may be artificially synthesised in the laboratory. The vegetable alkaloids quinine, morphine and atropine, have been isolated within the last century; and the syntheses of citric acid and indigo have been effected from their elements. The isolation of the animal alkaloids may be more difficult, but it will be accomplished—some have already been obtained, others will follow; the isolation of the antitoxins will be the next chemical triumph, and then will come the synthetical production of these life-saving substances. At University College, Prof. R. Russell begged his hearers to cultivate the spirit of scientific inquiry. Every scientific investigation, if properly conducted, might be expected to disclose some new fact, and this was the only way in which true progress could be made. It was to men of science that every real fresh advance in medicine was due. The so-called practical man could do little more than apply and utilise the discoveries of the investigator. A belief prevalent among some people, that a man could not be both scientific and practical, and that the cultivation of the one spirit must of necessity be at the expense of the other, he regarded as a great fallacy. Medicine and surgery could only be expected to be advanced by a proper commingling of the scientific and the practical, so that scientific principles might find practical application in the elucidation and treatment of disease. At the London School of Medicine for Women, Dr. F. W. Andrewes also referred to the intimate relation between scientific studies and medical practice. He remarked, for instance, that the methods by which pathology is studied are precisely those used in other pure sciences—observation and experiment—and it is this science which is placing medicine and surgery on a scientific basis. It is obvious that a sound knowledge of disease is an indispensable preliminary to its reasonable treatment. At the Royal Veterinary College, Prof. Crookshank discussed the subject of the relation between human and bovine tuberculosis. Dr. A. P. Luff, at the Pharmaceutical Society, commented upon the too general use of powerful drugs in compressed forms, and of proprietary preparations, in the treatment of disease. Addresses were also given by Dr. W. Hill at St. Mary's Hospital, and Dr. T. H. Kellock at Middlesex Hospital.

THE forty-sixth annual exhibition of the Royal Photographic Society was opened to the public on Monday at the New Gallery, Regent Street, and although the greater part of the available space is occupied by exhibits of the artistic and professional kinds, there is an important section devoted to scientific and technical examples. Among a considerable number of natural history subjects there is a notable series, that has been awarded the Society's medal, by Mr. Douglas English. He shows six frames, each containing three or four different photographs of the brown rat, the common mouse, the wood mouse, the field vole, the bank vole and the water vole respectively. The photographs are not of a haphazard kind, for in spite of the difficulties of the subjects Mr. English has succeeded in giving typical front and side views of each species. A series of waves and ripple marks in water, sand, snow and clouds, by Dr. Vaughan Cornish, and another of typical cloud forms, by Captain D. Wilson-Barker, are good examples of the kind of work that may be done in this direction. M. Henri Becquerel has contributed several interesting examples of the effects of the mysterious rays that emanate from uranium and radium, including their deviation in a magnetic field and the separation of the different kinds of rays. Recent spectrum work of various kinds is also shown. A series of radiographs by Dr. Hall-Edwards is of especial interest as they were made at the Imperial Yeomanry hospitals at Deelfontein and Pretoria a few months ago. They show bullets in different parts of the body, including the chest, and the effects of soft-nosed and expansive bullets. In the Exhibition there will be found a fine collection of examples of various methods of photomechanical work. A panorama of the great working hall of the German Electrical Co. is a remarkable photogravure nearly five feet in length, by Messrs. Meisenbach, Riffarth and Co., but the most notable exhibits in this section are the colour prints. Three-colour prints by the method of superposed films, superposed carbon prints, and the ordinary three-colour typographic work, photogravure in colours and colour collotypes, may be seen at their best. Those who appreciate the curious in this direction may examine gum bichromate prints in three colours, and colour effects produced by exposing gelatino-chloride paper through green leaves. Among the new apparatus the European Blair Camera Co. have contributed their new film cartridge, in which the numbers and dividing marks are simple perforations through white paper, showing the black beneath, and therefore cannot have any effect on the sensitive surface.

THE Cunard steamer *Lucania*, which arrived at Liverpool on Saturday morning, reported that, on September 25, she had been in communication at sea by wireless telegraphy, with the same company's outward bound steamer *Campania*, which left Liverpool on September 21. The ships were 36 miles apart when complimentary messages were exchanged, and were not visible to each other at any time.

THE annual "cryptogamic meeting" of the Essex Field Club will be held on Saturday, October 12, at High Beach, Epping Forest. Dr. M. C. Cooke, Mr. Massee, Prof. Marshall Ward, F.R.S., and other botanists have consented to act as referees. Prof. Marshall Ward will give an address on "The Scientific Study of Fungi." Botanists and others wishing to attend should communicate with the hon. secretary, Mr. W. Cole, Buckhurst Hill, Essex.

WE learn from the *Times* that a statue of Pasteur was unveiled on Sunday at Arbois, where he spent his childhood and where he latterly spent his few holidays. Pasteur's son and his son-in-law, M. Vallery Radot, were present, and almost the whole population of the little town assembled round the statue. M. Decrais, Minister of the Colonies, in a glowing eulogium on Pasteur, stated that in the hope of earning for France the honour of preventing the ravages of yellow fever, Drs. Marchoux and Simon, nominated by the Pasteur Institute, and M. Salimbeni, an eminent Italian, were about to be sent to Brazil to study the malady. M. Liard, of the Institute, also spoke on Pasteur's achievements and character.

PROF. G. SIMS WOODHEAD contributes to the *Monthly Review* an article upon the prevention and cure of tuberculosis, with special reference to the conclusions stated by Prof. Koch in his address to the recent British Congress on Tuberculosis.

THE last two numbers received of Engler's *Botanische Jahrbücher* (vol. xxx. Heft 2 and vol. xxxi. Heft 1 and 2) contain several important systematic papers—a monograph of the Diseæ (a section of Orchideæ), by R. Schlechter, and a monograph of *Mahonia*, by F. Fedde—a report on the botanical results of the Lake Nyassa and Kinga Mountain Expedition, by Prof. Engler; and a very interesting short paper by E. Ule on ant-gardens in the Amazon region. Several species of ants appear to collect the seeds of the "ant-epiphytes" and carefully bury them in humus, covering up and protecting the young plants when they germinate, and thus producing veritable gardens often of considerable size. Quite a number of these epiphytes—three Araceæ, five Bromeliaceæ, five Gesneraceæ, one Moraceæ, two Piperaceæ, one Cactaceæ—were found by Ule in these gardens and nowhere else.

THE Society for the Protection of Birds is this year offering two prizes, of 10*l.* and 5*l.* respectively, for papers on the best means of establishing a "Bird and Arbour Day" in England. In many of the schools of the United States bird days and arbour days have become a very popular institution, and have proved most successful in interesting teachers and children in birds and bird protection; and the Society's offer will, it is hoped, elicit practical hints as to the way in which the scheme may be introduced and worked in English schools. Papers are to be sent in not later than November 30, 1901, and all particulars may be obtained of the Hon. Secretary, Society for the Protection of Birds, 3, Hanover-square, London, W.

DR. T. E. THORPE's report upon the work of the Government Laboratory has recently become available. From the large amount of work described in the report, we select a few points for mention. It appears that since the Act was passed limiting the amount of moisture in tobacco to 30 per cent., manufacturers have been using an excessive quantity of oil in roll and cake tobacco. An Act was therefore passed last year limiting the proportion of oil to 4 per cent., and a process for the estimation of the amount of oil has been devised. Liquorice, glycerine, and salicylic acid are other substances found in adulterated samples of tobacco. Two samples of British-grown tobacco were received at the Government Laboratory from two small lots of tobacco which had been grown in England by persons who had not received the permission from the Board of Inland Revenue to grow tobacco—such permission is necessary even for experimental cultivation. A sample of pemmican was examined for the Committee of the National Antarctic Expedition. It was supposed to be quite free from moisture and to contain 60 per cent. of ox lard with a highly nutritive base, but on examination it was found to contain 8 per cent. of moisture and 38 per cent. of starch, whilst the total amount of fat present was only 19·6 per cent. Many other instances of adulterated goods and variation of quality are given by Dr. Thorpe. Thus, in ten samples of india-rubber the proportion of vulcanised rubber was found to vary between 5·7 and 44 per cent. Analyses made for the War Office showed that several samples of so-called butter were margarine; baking powders have been found to contain 67 and 75 per cent. of starch; cocoa paste has yielded 41 per cent. of water and only 23 per cent. of real cocoa; a sample of mustard contained 60 per cent. of added flour; strawberry jam 10 per cent. of other fruit, and many other jams and marmalade large proportions of glucose; oatmeal, flour and arrowroot were found of inferior quality, and so on. Among the drugs examined was a sample of effervescing phosphate of soda, which on analysis was found to contain arsenic equal to 4·62 grains of arsenious oxide per pound. The samples examined for the India Office were of the usual wide range. Gold-leaf is required to contain not less than 97 per cent. of pure gold, but in one instance a sample contained 5 per cent. of silver and only 91 per cent. of gold; type-metal is to consist of 65 parts of lead, 30 parts of antimony and 5 parts of tin, and yet in eight samples received together, the lead varied between 65 and 82 per cent., the antimony between 15 and 29 and the tin between 0·6 and 5·5 per cent.; antimony is required to contain less than 3 per cent. of impurities, but of five samples two contained 5·76 and 4·15 per cent. of impurity respectively. The functions of the Government Laboratory are evidently exercised over a wide field, and national interests are promoted by such analytical work as is carried on under Dr. Thorpe's direction.

IN *Symons's Meteorological Magazine* for September, Dr. H. R. Mill, who accompanied the Antarctic exploring vessel *Discovery* as far as Madeira, gives some details of the arrangements for taking observations. During the voyage out meteorological observations will be made every two hours, and these will be kept up subsequently to supplement those made at the land station. For the ordinary routine observations a form of Stevenson's Screen is erected in a position where a current of air will be blowing, when the vessel is under way. Rainfall observations are to be attempted by means of a marine rain-gauge and evaporator on Dr. Black's pattern. The position presented much difficulty; the method finally adopted was to place the gauge on the weather side, shifting it whenever the ship changes her tack, while the evaporator occupies a position on the lee side. The whole of the meteorological work on board is under the charge of the first officer, Lieutenant C. Royds. It is intended to make special observations in the Antarctic regions on the conditions of the upper atmosphere, and for this purpose a captive balloon and kites are provided. A Dines' pressure anemometer will be erected at the land station. The oceanographical observations to be made during the voyage will be under the charge of Lieutenant E. H. Shackleton, while Lieutenant M. Barne will take charge of the deep-sea soundings after leaving Melbourne.

A REMARKABLY simple astatic galvanometer is described by M. G. Lippmann in the *Journal de Physique* for August. It consists essentially of a fixed coil, or in practice two coils, and a needle suspended in such a way as to be capable of displacement parallel to itself. The needle is placed with its axis coinciding with that of the coils, and pointing in the plane of the magnetic meridian. It is suspended by a thread from one arm of a torsion balance. Now the earth's magnetism has no tendency to produce displacements of pure translation in a magnetised needle, and since it is these displacements which alone are observed, it follows that the earth exerts no force in opposition to that produced by the current in the coil; the apparatus is therefore perfectly astatic.

AN interesting phenomenon recently described in connection with the theory of sound forms the subject of a paper by Mr. Bergen Davis in the *Physical Review* for June. The property in question is that if a small cylinder, closed at one end and open at the other, is placed in a stationary sound-wave, it will not only arrange itself perpendicular to the wave, but will also move across it in the direction of its axis. By arranging four such cylinders on a rotating mill, like the cups on an anemometer, and placing this mill with its axis of rotation perpendicular to the wave front, it was found that on sounding the organ pipe producing the waves, the cylinders rotated with a high velocity, except when placed at the nodes. The phenomenon is readily explained as a consequence of Bernouilli's well-known relation between the pressure, density and velocity of a fluid.

MAXWELL'S theory, which attributes electric and magnetic phenomena to tensions and pressures in the medium that forms the seat of electric and magnetic energy, has long been a subject for criticism. In the *Nuovo Cimento*, 5, ii., Signor Luigi Giuganino now advances certain considerations arising from a mathematical investigation of the tensions in the interior of a fluid polarised magnetically or dielectrically. The author finds, among other results, that if the polarised body is compressible and behaves like a fluid body, and only carries induced charges, it is impossible to find a system of elastic stresses equivalent to the given polarisation. If, however, the polarised body is considered to be an imperfect fluid, either there exist an infinite number of systems of tensions and pressures equivalent to the polarisation, or no such system exists. The expression for these tensions and pressures does not, however, reduce to Maxwell's and Helmholtz's formula. Signor Giuganino further advances the view that the elastic constant of the fluid when polarised assumes different values along and perpendicular to the lines of force, and that herein lies the explanation of Kerr's phenomenon.

IN the last *Bollettino* of the Italian Seismological Society, Prof. Grablovitz describes a simple and inexpensive form of recording tide-gauge, the total cost of which he estimates at less than 7*l.* 10*s.* The movements recorded are those of a spiral spring the length of which changes with the varying amount of immersion of a cylinder suspended from it.

IN continuation of his previous reports, Mr. S. Arcidiacono describes the principal eruptive phenomena which occurred in Sicily and the adjacent islands during the year 1900 (*Boll. della Soc. Sismol. Ital.* vol. vii. 1900, pp. 82–91). After the great explosion in the central crater of Etna on July 19, 1899, and the short eruptive period which succeeded it, that volcano remained in a state of almost uninterrupted calm. Stromboli continued in its usual condition of slight activity, varied by a few stronger outbursts, especially in the early part of October. The solfataric phase of Vulcano and the absolute calm of the Salsa di Paterno underwent no change throughout the year.

A CATALOGUE of the marine invertebrata of Eastern Canada, by Dr. J. F. Whiteaves, has also been published by the Geological Survey of Canada (1901). It consists of a systematic list of all the species described from the Bay of Fundy, the Atlantic coast of Nova Scotia, the Gulf and mouth of the River St. Lawrence, as far north as the Strait of Belle Isle. The localities at which some of the species are found fossil in the Pleistocene deposits are also briefly indicated.

DR. G. A. F. MOLENGRAAFF, who was formerly State Geologist to the South African Republic, has written an excellent account of the geology of the Transvaal Colony, which has been published by the Geological Society of France (*Bulletin*, 4e serie, vol. i. 1901). It is accompanied by a colour-printed map, and many pictorial views and sections.

A SIXTH edition of Mr. Whitaker's useful "Guide to the Geology of London" has just been issued by the Geological Survey. The first edition was published in 1875, and in the present edition the work has grown to the extent of thirty pages, partly owing to an increased number of illustrations, including fossils, flint-implements, and sections of strata. The work has been brought thoroughly up to date, and the price remains one shilling.

WE have received from the Geological Survey of Canada the Annual Report for the year 1898 (Ottawa, 1901). This includes the Summary Report, and also a report on the mineral statistics, previously noticed in NATURE (June 15 and September 20, 1899). There are also reports on the shores of Lake Winnipeg, on those of Hudson Strait, and on Quebec province. In these the fossils of the Cambro-Silurian or Ordovician rocks of Manitoba and of Quebec receive especial attention, and there are full descriptions of the glacial phenomena. There is a good view showing the character of the surface of the Archæan rocks in Keewatin, and many other photographic illustrations of scenery and geological structure.

MR. J. J. WILKINSON has forwarded us a copy of a pamphlet giving an account of the very large and remarkable pharynx of the fly-larvæ commonly known as rat-tailed maggots, which are sometimes seen so abundantly in water. The pamphlet, which is illustrated with two plates, is published by Messrs. R. Clay and Sons, Ltd.

THE *American Naturalist* for September contains only two original communications—the one a continuation of Prof. W. M. Wheeler's account of the compound and mixed nests of American ants, and the other of Prof. H. S. Jennings' synopsis of North American invertebrates. The particular description of social ant-life treated of in Prof. Wheeler's article is that commonly known as slavery, and technically as "dulosis." Instead of slaves, it is suggested that a better title for the subservient ants would be helpmates, or auxiliaries, for the members of the two species found in the same nests behave towards each other as if they were brothers and sisters, and share the task of constructing the habitation. Unlike that which obtains in other kinds of ant-association, the so-called slaves always belong to the same subfamily group as their masters.

IN their Report for 1900 the trustees of the South African Museum remark that "the public events of the past year have, naturally, affected the Museum in more ways than one. Both the number of contributions to the collection and the number of visitors to inspect them have fallen off to a considerable extent. This is the first break in a continuous increase prolonged over a lengthened period." In spite of these discouraging circumstances, it is nevertheless hoped that substantial progress has been made both in regard to the development of the Museum and the extension of our knowledge of the South African fauna. During the year in question were issued Mr. W. L. Sclater's two volumes on the mammals of South Africa and the late Dr. Stark's volume on the birds, all of which have been noticed in our columns. The Director announces that, with the aid of the MS. left by Dr. Stark, he has completed the second volume on the birds, while the third is in hand. The Museum has been enriched by specimens of several mammals from Mr. Rhodes's park at Groote Schuur.

AN interesting and well-illustrated account of the growth and present condition of the Millport Marine Biological Station, or, as it is now called, the Marine Biological Association of the West of Scotland, appears in *Good Words* for September. As many of our readers are aware, this admirable institution, which is so largely indebted for its progress to Sir John Murray and had very small beginnings, was started to commemorate the life-work of David Robertson, the "naturalist of Cumbrae." And it is satisfactory to learn that the "Robertson Museum," occupying the upper part of the main building of the station, attracts during the season a large number of visitors, many of whom display much interest in the living creatures from the Firth of Clyde exhibited in special tanks. From its humble beginnings in the well-remembered "Ark"—a barge given by Sir J. Murray—the author traces the gradual progress of the station, which has been recently enriched by the gift, from an anonymous donor, of a deep-sea dredging steamer, and likewise by a five-year endowment from the same generous hand. As an instance of the manner in which commerce is benefited by undertakings of this nature, Mr. Sinclair tells us how the discovery of large deep-water shrimps in the Scotch lochs led to their detection in the still deeper fjords of Norway, with the result that the Norwegians now do a flourishing trade in these deep-sea crustaceans.

IN a very interesting memoir which has recently appeared in the *Proceedings* of the American Academy of Arts and Sciences (vol. xxxvi. No. 20, March 1901) Messrs. T. W. Richards and E. H. Archibald give a preliminary account of the series of investigations they are carrying on in the chemical laboratory of Harvard College on the growth of crystals. Ever since the discovery of the microscope, the gradual growth of crystals in a solution has proved a fascinating study, but the sudden way in which the embryo crystals flash into existence and the insensible manner in which they enlarge their dimensions appear to defy the acutest observer. Vogelsang introduced the method of retarding the action of the crystallising forces by adding viscous materials to the solvent, and his study of globulites and other forms of embryo crystals has been the starting-point of many important physical investigations by O. Meyer, Ostwald and others. The two American investigators, with the aid of a grant from the Rumford Fund, are now applying the method of instantaneous photomicrography to the study of growing crystals. In their first memoir they discuss the methods of procedure and give illustrations of some of their results, which appear to be full of promise.

ANTHROPOLOGISTS and folklorists would find it worth their while regularly to look over the pages of *Globus*, as in that well-edited journal there are constantly interesting and often illustrated articles and notes which are of permanent value. For example, in No. 23, Bd. lxxix., there is an essay by Julius von Negerlein on souls as birds, and a well-illustrated article on West African masks and the ceremonies with which they are associated, by Dr. Karutz. R. Palleske gives an illustrated account of a find at Ingelstad, in Sweden, of a horse's skull in which is embedded a very fine stone axe head of a form characteristic of the later half of the (Neolithic) Swedish Stone age; as it is highly probable that the horse did not exist in its wild state in Sweden after the Quaternary period, the conclusion is arrived at that in the late Neolithic age the horse was domesticated in Sweden. The original account of this interesting find was published by Gunnar Andersson, in *Ymer*, 1901, heft i. In No. 1, Bd. lxxx., F. von Luschan gives an illustrated description of a new kind of masks from New Britain, Dr. A. Krämer discusses phallic and other sacred stones from the Pacific and Dr. L. Rütimeyer figures two "stone idols" from West Africa. In No. 7 Dr. R. Lasch publishes a learned study on the fate of the souls of women who die in child-bed. All over the world there are beliefs of the disastrous results of this calamity; thus in the Malay Peninsula "the Pontianak" (or Mati-anak, as W. W. Skeat also calls it in his "Malay Magic," which book the author appears to have overlooked) "is supposed to be the ghost of a woman dying in child-bed, and is commonly seen in the form of a huge bird uttering a discordant cry. It haunts forests and burial grounds, appears to men at midnight, and it is said to emasculate them."

THE *Transactions* of the American Microscopical Society for 1900 (issued May, 1901), contains papers on a great variety of subjects, ranging from the surface impurities affecting water-supply and "limnology" (the study of lakes), to the classification of desmids and microscopic crustaceans, the parasites of the human ear and of lacustrine fish, and the description of a new cave salamander from Missouri. The latter, it may be observed, is another member of the already large American genus Spelerpes. A special feature of the volume is the first report of the newly constituted Limnological Commission, whose aim is to institute an exhaustive biological and physical investigation of the American lakes, on the plan already carried out with such success in Switzerland.

THE third instalment of Messrs. W. and G. S. West's "Alga-Flora of Yorkshire," reprinted from the *Transactions* of the Yorkshire Naturalists' Union, completes their list of the Conjugatæ (Desmidieæ) of the county, and enumerates the Siphoneæ, Protococcoideæ, and Cyanophyceæ (Myxophyceæ), with the commencement of the diatoms (Bacillariaceæ).

WE have received from Mr. J. H. Maiden, Government Botanist and Director of Botanic Garden, Sydney, copies of about thirty papers contributed by him during the years 1896–1901 to the *Agricultural Gazette* of New South Wales, and reprinted by the Department of Agriculture for the Colony, all relating to some point of interest or importance to farmers, gardeners, or fruit growers in the Colony.

IF sufficient support can be obtained, it is proposed to establish a new monthly journal, under the title *British Botanical Journal*, to afford a ready means of communication and discussion among British botanists. The contents will consist of articles and reviews, short paragraphs on important and striking current botanical matters, correspondence, short notices of books, original papers and notes, &c. Communications should be addressed to Mr. A. G. Tansley, University College, London, W.C., who will be the first editor.

Bulletin No. 28 of the U. S. Department of Agriculture, Division of Vegetable Physiology and Pathology, consists of an elaborate account, occupying more than 150 pages, of the cultural characters of the yellow flagellate bacteria *Pseudomonas Hyacinthi*, *P. campestris*, *P. Phaseoli*, and *P. Stewarti*, parasitic respectively on the hyacinth, on cruciferous plants, on leguminous plants, and on grasses, especially on maize. The favourable and unfavourable conditions for the growth of the parasites are treated of in great detail.

THE first part of a "Handbuch der vergleichenden und experimentellen Entwickelungslehre der Wirbeltiere," edited by Dr. Oscar Hertwig, has been received from the house of Gustav Fischer, Jena. The work promises to contain an exhaustive treatment of comparative and experimental embryology, and will be completed in about twenty parts at four-and-a-half marks each.

MM. GAUTHIER-VILLARS have commenced the publication of a complete "Cours d'Électricité," by Prof. H. Pellat. The work will be issued in three parts, the first of which, dealing with electrostatics, Ohm's law and thermoelectricity, has been received. The second volume will be concerned with electrodynamics, magnetism and induction, and the third with electrolysis, electro-capillarity and related questions. The part already received contains the course of work in electricity at the Sorbonne in 1898–1899; the second part will contain that carried on in 1899–1900, and the third will correspond to the course to be followed next year.

A NEW edition of "The Evolution of Sex," by Profs. Patrick Geddes and J. Arthur Thomson, reviewed in NATURE in 1890 (vol. xli. p. 51), has been published by Mr. Walter Scott. "In this revised edition," say the authors, "though many alterations and additions have been made, the original character of the work has been retained, and that notwithstanding the difficulty that the authors have in the past ten years been diverging biologically—the one towards a Neo-Lamarckian position, the other towards a Neo-Darwinian one. Yet they remain agreed on the main endeavour of the book, which is to set forth the fundamental unity underlying the Protean phenomena of sex and reproduction."

A NEW scientific periodical, the *Allgemeine Naturforscher-Zeitung*, edited by Dr. C. Wenck, commenced its career on October 2, and will appear twice weekly. The aim of the Editor is to publish scientific papers very shortly after they have been presented at meetings or congresses, and to make the journal reflect the chief characteristics of current scientific work. The first number contains two papers—one on anabiosis and the other on electrons—read at the recent Congress of Naturalists and Physicians at Hamburg, and a number of abstracts and reviews. In general character, the new periodical does not differ much from the old-established *Naturwissenschaftliche Wochenschrift*, which has just commenced a new series under the editorship of Prof. Potonié and Dr. F. Körber, and is now published by Mr. Gustav Fischer.

THE additions to the Zoological Society's Gardens during the past week include a Ring-tailed Lemur (*Lemur catta*) from Madagascar, presented by Mr. Chas. Rawsthorne; two Jays (*Garrulus glandarius*), British, presented by Mr. W. Radcliffe Saunders; three Common Snakes (*Tropidonotus natrix*), British; a Viperine Snake (*Tropidonotus viperinus*), European, presented by the Rev. H. A. Soames; a King Crab (*Limulus polyphemus*) from the North Atlantic Ocean, presented by Mr. Walker; two Arabian Baboons (*Cynocephalus hamadryas*, ♂ ♀) from Arabia, a Nilgiri Thar (*Hemitragus hylocrius*, ♂) from Southern India, four Getulian Ground Squirrels (*Xerus getulus*) from Morocco, four Great Wallaroos (*Macropus robustus*) from South Australia, an African Civet Cat (*Viverra civetta*) from South Africa, two Malayan Wrinkled Hornbills (*Rhytidoceros undulatus*) from Malacca, six Gigantic Salamanders (*Megalobatrachus maximus*) from Japan, four American Box Tortoises (*Cistudo carolina*) from North America, six Ceylonese Terrapins (*Nicoria trijuga*), nine Starred Tortoises (*Testudo elegans*) from India, a Lesueur's Water Lizard (*Physignathus lesueuri*) from Queensland, a Bearded Lizard (*Amphibolurus barbatus*) from Australia, deposited; a Rufous-necked Wallaby (*Macropus ruficollis*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

DIAMETER OF VENUS.—In the *Astronomical Journal* (vol. xxii. pp. 13–15), Mr. D. A. Drew gives the results of a series of measures of the diameter of Venus, made with the 24-inch refractor of the Lowell Observatory at Flagstaff, Arizona, in 1898. For the majority of the determinations a power of 165 was employed, together with an ocular diaphragm half a millimetre in diameter and an amber-coloured glass screen.

The tabulation and discussion of the reduced diameters indicates that there appears to be a peculiar variation in the planet's diameter, decidedly periodic, which may be due partly to the variable irradiation with the different phases and brilliancy of the body at different times.

SPECTRUM AND APPEARANCE OF NOVA PERSEI.—Herr E. von Gothard announces in *Astronomische Nachrichten* (Bd. 156, No. 3738) that he has photographed the spectrum of the Nova with a 10½-inch reflector and objective prism, the result showing many of the characteristics of the peculiar structure seen in the spectra of planetary nebulæ. Bright lines are present at λλ 5007, 4861 (H_β), 4341 (H_γ), 4101 (H_δ), 3970 (H_ϵ), 3867, and a new line about λ 342. The brightest line in the whole spectrum is that at λ 3867, which is very prominent in planetary nebulæ.

He also alludes to the possibility of the aureole shown surrounding the star on photographs obtained with refracting telescopes being produced by the non-achromatic correction of these glasses for the extreme ultra-violet rays, which are so strongly developed in the Nova spectrum as to produce the chief part of the photographic action. This view of the question is also mentioned by Prof. Max Wolf in No. 3736; in

No. 3737 Skostinsky gives observations made at Pulkowa on the aureole and spectrum. The lines given are as follows:—

	λ		Intensity
1901 August 2	5010	Fairly bright line ...	10
	4960	Weak	2–3
	4861	Hβ	5
	4703	Bright, very broad...	6

ELEMENTS OF COMET 1901 I.—Mr. C. J. Merfield publishes the computed elements of the orbit of this comet in *Astronomische Nachrichten* (Bd. 156, No. 3738). The reductions are from observations made by Mr. J. Tebbutt on 1901 May 3, 11 and 19.

$$T = 1901 \text{ April } 24{\cdot}22532 \text{ G.M.T.}$$

$$\left.\begin{array}{l} \omega = 202^\circ\ 48'\ 46'' \\ \Omega = 109\ 46\ 23 \\ i = 131\ \ 2\ 35 \end{array}\right\} 1901{\cdot}0$$

$$\log e = 9{\cdot}9983750$$

THE GLASGOW MEETING OF THE BRITISH ASSOCIATION.

SECTION K.

BOTANY.

OPENING ADDRESS BY PROF. I. BAYLEY BALFOUR, LL.D. (GLASG.), F.R.S., PRESIDENT OF THE SECTION.

I SHOULD be wanting in my duty, alike to you and to our science, were I at the outset of our proceedings to pass over without notice the circumstances of environment in which we assemble to-day. In this, the first year of the century, our Section meets for the first time in Scotland, and finds itself housed in this magnificent Botanical Institute, which, through the energy and devotion of Prof. Bower, has been added this year to the equipment of Botany in this country. A few months ago the Institute was opened in the happiest auspices and with all the distinction that the presence of our veteran botanist, Sir Joseph Hooker, supported by two other ex-Presidents of the Royal Society—Lord Lister and Lord Kelvin—could give to the ceremony. I am sure we will cordially echo the words of goodwill that were spoken on that occasion. It must be to all of us a matter of congratulation that Botany has now provided for it in Glasgow this Institute both for its teaching and for the investigation of its inner secrets, and we may with confidence hope that the output of valuable additions to our knowledge of plant-life which has marked Glasgow during the tenure of office of its present distinguished Professor of Botany, and in which he himself has borne so large a share, will not only continue but will increase in a ratio not incommensurate with the facilities that are now provided.

The subject of my address is the group of Angiosperms. I will speak generally of some points in their construction from the point of view of their position as the dominant vegetation of the earth's surface at the present time, and more particularly of their relationship to water, as it is one which has much to do with their holding the position they now have. I wish, however, in the first place to refer to

The Communal Organisation of Angiosperms.

No fact of the construction of the plant-body that has been established within recent years is of greater importance than that of the continuity of protoplasm in pluricellular plants. As has been the case with so many epoch-making discoveries, we owe our first knowledge of this to the work of a British botanist. The demonstration by Gardiner of the existence of intercellular protoplasmic connections is the foundation of our modern notion of the constitution of the pluricellular plant-body and of the far-reaching conception of the communal organisation of Angiosperms and of all other Metaphyta.[1] It has settled, once and for all, phytomeric hypotheses. We now realise that in an Angiosperm the living plurinucleated protoplasm is spread over a skeletal support furnished by the cell-chambers of shoot and root. The energid of each living cell is connected with the adjacent energids by the protoplasmic threads piercing the separating cell-membrane. The protoplasm thus forms a continuous whole in the plant. According to their position in the organism the energids become devoted to the formation of special tissues for the building up of the various organs. Each one of them, however, whilst its actual destiny is ultimately determined by its relationships to the others, is, so long as its fate as a permanent element is not fixed, a potential protophyte, that is to say, it has within it all the capacities of the plant-organism to which it belongs.

Their construction out of this assemblage of protophytes—this colonial, or perhaps better communal, organisation—gives to Angiosperms their power of discarding effete and old parts of the plant-body without mutilation, of allowing these to pass out of the region of active life yet to remain without damage to the organism as part of the body, of renewing and replacing members as required. The response of the plant to the various horticultural operations of pruning, propagation by cuttings, and so forth is an outcome of this constitution. It is this which gives them the power of developing reproductive organs at any part of the plant-body, to cast them off when their work is done, and to renew them again and again. This dispersion of the reproductive capacity in the Angiosperm is one of the most striking of the properties it possesses, and is perhaps in no way better shown than in the development of stool-shoots. There the energids of the cambium, which normally produce the permanent tissue of wood and bark, and thereby add periodically to the girth of a tree, give origin when the relationships are changed by the cutting over of its bole to a callus from which stool-shoots arise as new growths, which may ultimately produce flower and reproductive organs.

Another outcome of this organisation of the Angiosperm is its power of extension and its longevity. It is potentially immortal. How far this expectation of life of a plant is realised in nature we have no evidence to show. Possibly we may presage the longest life in the case of perennial herbs. Trees and shrubs by their exposure in the air are liable to injury which must militate against long life, and yet cases of trees of great age are well known to you all.

It is this feature of the life of Angiosperms which marks them out sharply in contrast with the higher members of the animal kingdom. There we have individuality, and consequently comparatively short life. Let me emphasise this.

Of the Vegetable Kingdom and the Animal Kingdom.

The root-difference between plants and animals is one of nutrition. Plants are autotrophic, animals heterotrophic.

Whatever has been the origin of the two kingdoms, we must trace the differentiation of plants to their acquisition of chlorophyll as a medium for the absorption of the energy of the sun. The imprint of its operation is borne in the construction of all higher plants and distinguishes them from animals. The vegetative mechanism of the plant has been elaborated upon lines enabling it to obtain the materials of its food from gases and liquids which it absorbs from its environment. For the plant the primary requisite has been a sufficient surface of exposure in the medium whence it could obtain energy along with the gases and liquids of its food. To this end the fixed habit is an obvious advantage, for the question of bulk within the limits of nutrition becomes thereby not a matter of moment; and an upward and a downward extension gives opportunity for the creation of a larger expanse of absorptive surface. Thus it has come about that the plant-organism has developed that polarity which finds expression in the profuse root-system and shoot-system with their localised growing points of the highest forms of to-day. That the communal organisation is well fitted to this mode of life requires no exposition.

The nutritive mechanism of animals, on the other hand, has become one for the ingestion of solids which it obtains by preying upon the bodies of plants and other animals. The exigencies of its feeding have compelled the adoption by the animal of the habit of locomotion, the development of an apparatus for the capture of its prey, and of an alimentary canal for its introduction to the body, for its digestion, and for the final ejection of the unused matter along with the waste of the body. This has

[1] Metaphyta and its antonym Protophyta are well-established names for groups of polyergic and monergic plants respectively. The recent appropriation of Metaphyta as a group name for Vasculares, *i.e.* plants derived from the second antithetic generation, and of Protophyta for Cellulares, *i.e.* plants derived from the first antithetic generation, is unfortunate.

involved the concentration and the specialisation of the individual.

All this is, however, to you botanists but the commonplace of your laboratories and lecture halls. But I have thought that it should be said, because this fundamental difference of organisation between the two kingdoms is apt to be forgotten in discussions of problems of evolution, more particularly those of transmission of characters and the effect of environment. This is especially so when they are approached from the zoological side. Were the point always recognised we should not have zoologists finding similarity between bud-variation in a flowering plant and the change in colour of the hair of a mammal.

Of Origin and Dominance of the Angiospermous Type.

It is now usually admitted that all plants, like all animals, have been derived from aquatic ancestors, and that the trend of evolution has been in the direction of the establishment of a vegetation adapted to a life on land. Of this evolution the Angiosperms as we see them to-day are the highest expression. Can we say anything about the origin of the angiospermous type? As the problem presents itself to me we can only mark time at present.

From the geological record we obtain no help. The earliest traces of Angiosperms in rocks of the middle Mesozoic period enable us to say little regarding them except that the fragments give evidence of an organisation as complete as that possessed by the Angiosperms of the present day. The gap between the angiospermous and other types of vegetation is a wide one, and no links are known. Until further research provides specimens in a better state of preservation and showing structure we can hope for little assistance from the geological record; and when we consider the circumstances in which the angiospermous plants as a whole grow the prospect of such finds does not appear to be very bright.

The appeal to ontogeny likewise gives us little information. Comparative study does not establish connection with, only differentiates more and more, the types of the Pteridophytes and Gymnosperms. The strong likeness of the pro-embryo after the primary segmentation of many Angiosperms to the pro-embryo of many Bryophytes has appeared a sufficient reason to some botanists for ascribing a bryophytous parentage to the Angiosperms. Indeed it has been said that "the monocotylous embryo is the direct homologue of the sporogonium of the moss, the cotyledon being homologous with the spore-producing portion of this out of which it originated." This anaphytic conception of the monocotylous embryo seems to me to have as little real foundation as the hypothesis of its origin. The pro-embryonic resemblance is interesting, but it may as well be homoplastic as genetic.

But if the information available to us does not permit of our building up a pedigree for the Angiosperms, we are on surer ground when we endeavour to fix upon characters which have enabled the group to become established as the dominant vegetation of our epoch. Before the era at which we have first knowledge of Angiosperms the earth's surface was, we know, clad with a dense vegetation composed of members of the various classes of Pteridophytes and Gymnosperms. These appear to have existed in all the growth-forms which we know now amongst the Angiosperms—Herb, Shrub, Tree, Liane. Yet they are now represented amongst living plants by only a few remanent forms. Hordes of distinct forms and whole classes have disappeared, giving place to plants of the angiospermous type. There must then be some feature or features of advantage in this type over those of the groups that previously occupied the ground, and through which it became dominant.

In considering this point we must bear in mind the well-known climatic differences—particularly in the distribution of water—that distinguish our epoch from those in which these extinct plants throve. The factors which determine the success or otherwise of an organism or group of organisms at any period must always be complex, and no exception can be claimed for plants in their struggle for mastery. But looking at the succession of plant life in the world in relation to the known diminution of water-surface and increase of land-area, and the consequent differentiation of climates, we cannot but be convinced that of these factors water is one which has had supreme influence upon the evolution of the facies of the plant-life that we see to-day. I think the statement is warranted that the Angiosperms have become dominant in great measure because in their construction the problem of the plant's relationship to water on a land-area has been solved more satisfactorily than in the case of the groups that preceded them.

The seed character—and the flower which it involves—distinguishes the Angiosperms. What, then, are the relationships to water which the formation of seed implies and through which the Angiosperm has advantage?

Two prominent risks in its relation to water attach to the process of sexual reproduction in a plant of the type of heterosporous Pteridophytes. Firstly, that of failure of moisture on the soil sufficient to promote germination of the spores; secondly, that of failure of moisture on the soil sufficient for the passage of the spermatozoid to the ovum. In addition there is the risk of failure of the fall of microspores and megaspores together upon the soil. In the Angiosperms such risks are practically abolished in the formation of flower. The stigmatic surface of the style itself provides a secretion—the more copious in a dry and sunny atmosphere—to moisten the pollen-grain and stimulate germination, and for the spontaneous movement of the spermatozoid is substituted the passive carriage of the male gamete to the ovum by the agency of the pollen-tube. Possible failure of pollination is, too, provided against by the complex mechanism of the flower in the highest forms in relation to insect-visits. The sexual act, then, might, we conceive, gradually become more and more difficult of consummation to the Pteridophyte as the area of dry land increased. To the seed-plant it was more secure by its independence of the presence of free water. The failure of performance of the function of sexual reproduction may have hastened the disappearance of Pteridophytes before the advance of the Angiosperms.

But if this flower-mechanism relieves the Angiosperm from risks in the performance of the sexual act, it imposes a new duty upon the plant, that of nursing the embryo within the sporangium. This involves a water-supply of a kind not demanded in the Pteridophytes, and we may gain some idea of the importance of this by a comparison of the trivial vascular system required to supply through the stamen the pollen-grain, with the copious system that traverses the gynæceum for the ovules. It is, however, to the ovule—the immediate nursery of the embryo—that we must look for special indications of this water-relationship of which I speak.

Perhaps no organ has given rise to more discussion than this characteristic one of flowering plants. To most of us I believe the controversy over its axial or foliar nature will be, in a measure, historical only. All recent investigations of sporangia—and to no one does Botany owe more in this respect than to Bower—tend to confirm the view that it is, and always has been, an organ *sui generis*. To that category the nucellus of the ovule is now pretty generally admitted. It is the body of a sporangium. But the nature of the tegumentary system and of the funicle which give the ovule so distinctive a character is still the subject of disagreement.[1]

I do not share a view which sees in the integuments or other parts of the ovule anything of an axial or of a foliar nature. To me the funicle is a sporangiophore—a sporangial stalk—and the tegumentary system is an outgrowth of the sporangial primordium of somewhat variable origin and development, whose first function it is to carry and store water for the embryo, and then also to serve as a food-reservoir. The whole construction is adapted to the function claimed for it. The well-developed vascular system from the placenta traverses the funicle, but the subsequent fate of the nucellus forbids its passing through this, and the needs in respect of water (and what it carries) of the embryo and of the other further developments that proceed in the embryo-sac are provided for by the production of the tegumentary outgrowths into which the vascular system may, if necessary, be continued and spread out.

That the tegumentary covering has this function we have direct proof in its penetration by haustoria, derived either from the embryo itself or from the embryo-sac, which absorb from it water and food for the developing embryo. These haustoria appear to be much more elaborate and more widespread than has been supposed, and a definite correlation has been established in many cases between them and the integuments. The thicker the integument the better developed is the haustorium.

[1] Scott's discovery of a bracteal investment to the megasporangium in Lepidocarpon is an interesting one in relation to the question of the enclosure of sporangia. It shows how in the Lepidodendreæ a covering of the sporangium could be developed, much in the same way as a carpellary envelope in Angiosperms. Whether the ovular integument or the ovarian covering in Angiosperms was the earlier development is open to discussion. I am disposed to give precedence to the ovular coat.

In some ovules where no vascular system appears in the integument, the chalazal haustorium is prominent, and it can therefore at once tap the main water-supply of the ovule. We know also of cellular ingrowths proceeding from the vicinity of the vascular system of the raphe to the interior of the embryo-sac, and these, too, may have a conducting function. All these point to a water and nutritive function in the integuments. The protective function of the tegumentary system to which attention has been chiefly directed must be primarily only slight. It only becomes prominent as the seed is formed, and then changes consonant therewith, and with its changed function, proceed within it. Nor can we now, with our increased knowledge of the ways in which the pollen-tube may reach the embryo-sac, consider the function of the integuments in forming the micropylar canal as one of so much importance to the reproductive act as was formerly supposed. We obtain, I think, a better conception of the ovule in the view that the primary function of the tegumentary system is that of a water-jacket and food-store, and that it has been developed in response to the special demands for water involved in the seed-habit.[1]

To the question why there are two integuments in some cases and only one in others we can only reply that our knowledge of ovular structure and changes is yet too slight to permit of a definite opinion being expressed. We find that there is a remarkable concurrence of the unitegminous ovule with a gamopetalous corolla in the flower, for the character apparently holds for the whole of the gamopetalous Dicotyledones excepting Primulales. On the other hand, not all Polypetalæ have bitegminous ovules, whilst bitegmeny is usual in Monocotyledones. Recently the character has been used by Van Tieghem as one of prominence in his new classification of the families of Dicotyledones. But it is not so constant an one as his groups of Unitegmineæ and Bitegmineæ would lead one to suppose. The degree in which it is inconstant we cannot yet fix, because we know details of so few genera. We do know, however, that all genera in one family are not always alike in respect of it. In Ranunculaceæ, for instance, the most of the genera with radial flowers are unitegminous, whilst those with dorsiventral flowers are bitegminous. Again, in Rosaceæ, the Potentillæ are unitegminous, as is Rosa, whilst Pomeæ and Pruneæ are bitegminous; and of the Spiræeæ, Neillia is unitegminous, but the closely allied Spiræa is bitegminous.[2] In other cases the character confirms distinctions; as, for instance, in separating the unitegminous Betuleæ and Coryleæ from the bitegminous Quercineæ. The explanation of all these constructions may, I suggest, be sought for with better prospect of success in the water-relationship and food-relationship of the integuments to the embryo than in protective function and relations to pollination. It is, perhaps, not without significance from this point of view that in, for instance, the Gamopetalæ such protective function as attaches to the tegumentary system in the seed is reduced or extinguished through the development of indehiscent fruits, accompanied in many Aggregatæ and higher Heteromeræ by the sinking of the gynæceum in the torus, and in many Bicarpelletæ by its enclosure in a persistent accrescent calyx.

All the information at our disposal seems to indicate that the tegumentary system of the ovule is extremely adaptive, and that its characters are not of themselves of much phyletic import. An extended examination of its characters as an organ of the nature I have depicted in relation to embryogeny is greatly needed. It is made all the more interesting by the questions of development of endosperm opened by the discovery of "double fertilisation." There is no more promising field of investigation than this, for it must yield results infinitely more interesting than the technicalities of formal morphology which have been for too long the stimulus to ovular research. I am tempted to go further and to say that it might supply an explanation of that most puzzling of subjects, the forms and curvature of the ovule. The common assumption that these have relation to pollination and make the advent of the pollen-tube at the micropyle easier is not altogether satisfactory. For the curvature not infrequently seems to place the micropyle in a position the opposite of favourable, and there is an absence of curvature in cases where it would appear to be desirable.

I will not dwell upon the subject of the seed itself as an advantage to the Angiosperm. Its construction follows upon the successful water-relation previously secured. We all know how its manifold adaptations to dissemination bring about its fortuitous deposition upon various soils, and the embryo is placed well guarded within the seed-coat ready to take advantage of the moment when moisture is sufficient for its germination.

Whilst the seed-habit is the character which has primarily given to Angiosperms their advantage as a land-type,[1] their vegetative organs also show an advance in their relationship to water upon those of the forms they have supplanted. I have already remarked that the growth-forms of the vegetation of the present day are the same as those of old. That means that the early as well as the later groups of vegetation have solved in much the same way, so far as general form is concerned, the problem of the exposure in the atmosphere of a large assimilating area with a sufficient mechanical support and adequate water-supply. That wherever a water-carrying system is found in these growth-forms it dominates the anatomy is witness to the importance of the water-relationships I wish to emphasise.

There are two features in the water-carrying system of Angiosperms in which they are superior to the older types—namely, their general monostely and their vasa.

No one will contest that polystely is a less perfect mechanism for water-carriage in a massive plant than is monostely. The limitation imposed by it to an increment in the area of carriage contrasts unfavourably with the openness in this respect possessed by monostely. In the moister climatic conditions of the age of domination of Pteridophytes polystely may have well sufficed for the water-needs of the plants, especially of the dwarfer forms; but even then, as we know, monostely was the habit in many of the larger tree-forms, and the development of a cambium enabled them to provide for continued additions to their carrying system. Where such monostely and secondary growth occurred in these older types their adaptation in these respects to water-carriage was on lines similar to those of our dominant Dicotyledones and was effective in giving them dominance in their epoch. There is no more interesting page in the history of evolution than that—and we owe it in large measure to the labours of Scott and Seward—upon which is depicted the struggle of some polystelic forms amongst these old plants to achieve the structural facilities more easily attained through monostelic construction. The existence of polystely in a few Angiosperms only confirms the advantage which the whole group has derived from its monostely. Such polystelic forms amongst them as we know have many of them special water-adaptations, and in no case can they be said to be progressive types.

I do not need to remind you that vasa are not the exclusive possession of the angiospermous type, but they are the conspicuous feature of their carrying system, whilst the tracheid is the leading one in the older type of vegetation. All anatomical evidence indicates that vasa give greater facility to rapid transport of water than do other elements, and we may, therefore, conclude that they have been adjuvants in enabling the Angiosperm to meet effectively the demand made upon it by the drier atmospheric conditions.

I now pass on to consider from the same standpoint the classes which make up the group of Angiosperms.

Of the Classes of Angiosperms.

There has been for long a general recognition of two classes amongst the Angiosperms—Dicotyledones and Monocotyledones—separated one from the other by definite characters which I need not specially depict here. Recently, however, we have seen an attempt made by Van Tieghem to establish another class—that of Liorhizal Dicotyledones—for which is claimed a rank equal to that of the Dicotyledones and Monocotyledones. Were this valid it would be a matter of supreme importance, for whatever be the relationship between Dicotyledones and Monocotyledones there can be no doubt of their having developed as

[1] To discuss the morphological interpretations of the funicle and integument that have been advanced would carry me beyond the scope of this address. I do not know that an axial hypothesis for any part of the ovule is now maintained. The foliar interpretation of the funicle and integuments as against their sporangial nature is supported by two distinct schools of botanists. One approaches the subject from the standpoint of the anaphytose of the earlier years of last century, and appeals largely to teratology; the other from that of vascular anatomy. I do not accept the starting-point of either the one or the other.

[2] Spiræa is, however, exalbuminous, whilst Neillia is albuminous.

[1] Gymnosperms, sharing with Angiosperms the seed-habit, have in that had advantage over Pteridophytes. But their flower-mechanism is much less perfect. The reasons for their being bested as a class by Angiosperms must be complex. Gymnosperms, as a whole as we know them, are less adaptive than Angiosperms. The decadence of the cycadean line of descent may have been helped by their conservatism in the methods of water-carriage in the vegetative organs. The coniferous type has held its own in the Northern Hemisphere.

distinct groups within the whole period of which we have knowledge of them, and the existence of a third class intermediate or outside of them might lead to interesting conclusions. It is worth while, therefore, to consider the evidence on which this class is founded. It includes two of our recognised families —the Nymphæaceæ and the Gramineæ.

What is the exact position and the affinities of the Nymphæaceæ amongst Angiosperms is no new theme of discussion. That they have characters resembling those of Monocotyledones[1] has often been insisted on. Van Tieghem lays stress on what he considers the monocotylous differentiation of the root-apex and the derivation of the piliferous layer from the same meristem-initials as the cortex, whilst in the embryo he finds the two cotyledons of Dicotyledones. But the most recent observations of the embryogeny of the family go to show that the embryo is that of the monocotylous plants, the apparent dicotylous character being the result of the splitting of one cotyledon. If this be so the position of Nymphæaceæ will be amongst the Monocotyledones, a position the root-characters in Van Tieghem's view will support. But whether this be confirmed by further research or no—and a complete reinvestigation of their embryogeny and development is much wanted—what we may say at present is that it is not in features such as this one of the root-apex—which is, after all, not so simple and uniform as Van Tieghem would have it—that we are likely to find phyletic diagnostic characters of groups.

The reason for the inclusion of the Gramineæ in this new group is the assumed presence of a second cotyledon. The construction of the embryo of grasses is peculiar, as is well-known, and has for a long time been a main support of the hypothesis that the Monocotyledones are derived from the Dicotyledones; for here alone, since the dicotylous character of forms like the Dioscoreæ was shown to be untenable, was there a structure which could be interpreted as evidence of a reduced second cotyledon. The idea that the epiblast is such a structure was enunciated by Poiteau at the beginning of the last century, and along with hypotheses of the nature of the other parts of the grass-embryo has been a subject of vigorous discussion since that time. The controversy is not yet closed. Whilst we have Van Tieghem now adopting the view of the cotylar nature of the epiblast and using it as a character of fundamental taxonomic importance, we have others who as strongly uphold the interpretation of it, first formulated by Gaertner, as a winged appendage of the scutellum, which is considered to be the cotylar lamella. And, again, there are those who take the view that it is a mere outgrowth of the hypocotylar body of the embryo and without any cotylar homology. Our interpretation of the part must depend primarily upon the standpoint from which we view the embryo of Angiosperms. This I shall discuss presently. All I need say here, *àpropos* of the class of Liorhizal Dicotyledones, is that whatever the epiblast be—and for my part I am disposed to regard this simple cellular structure as merely an outgrowth with a water-function from the embryonal corm—a dispassionate consideration must lead us to hold that it is a bold step to use a character the morphological value of which can be so variously interpreted as one of primary importance for separation of a group of Angiosperms. Moreover, we must remember that the feature of the epiblast is not one of universal occurrence in the Gramineæ. If we take a well-defined tribe like the Hordeæ, as framed by Bentham and Hooker, we find that of eight of its twelve genera which have been examined for this feature five have the epiblast and three want it. And surely the fact of its presence in Triticum and absence in Secale, its presence in Elymus and absence in Hordeum, is strong evidence that the epiblast is not a character of such importance as it would have were it a reduced cotyledon as is asserted.

It appears to me, therefore, that this third class of Angiosperms has no sound foundation, no more, perhaps less, than Dictyogens and Rhizogens which appeared as parallel groups with Endogens and Exogens in Lindley's old classification. Our present knowledge allows the recognition of only two classes of the angiospermous type—the Dicotyledones and the Monocotyledones.

Of Dicotyledones and Monocotyledones.

The relationship of these two groups is involved in the origin of the angiospermous type. They may have had a common origin or they may have arisen separately; and if the former the Dicotyledones may have been a subsequent offshoot from the Monocotyledones, or the reverse may have been the case. Each of these possibilities has its supporters. Were I to maintain an opinion it would be that the two classes have arisen on separate lines of descent. The embryo-characters, as well as those of the epicotyl, can, I think, be shown to be fundamentally different and to afford no basis for an assumed phyletic connection. The differences between Hepaticæ and Musci, to take a parallel case in a lower grade, are not more conspicuous. The parallel sequence in development in the two classes is no more than one would expect, and may be regarded as homoplastic. To the question which group is the older I would answer that the Dicotyledones are by far the most adaptive and progressive if—as is not necessarily the case—this can be taken as evidence of their more recent origin. This, however, is not the matter I intend to discuss here. I wish rather to inquire if there are any features broadly characterising the groups to which, as in the case of Angiosperms as a whole, we may look for help to an explanation of the predominance at this time of the type of Dicotyledones. I think there are, but they are not to be found in the reproductive system. That is constructed on sufficiently similar lines in each class. The features I refer to are to be found in the construction of the vegetative system both in the embryo and in the adult. That of the former gives the dicotylous plant an advantage in its start on life; that of the latter, both in shoot-system and root-system, is better adapted in Dicotyledones in relation to water-supply.

I specially differentiate the embryo-condition from the adult because in our consideration of these higher plants we are apt to overlook the two distinct stages into which their life is divided, and which call for altogether different adaptations. There is, firstly, the life in the seed and in germination; and, secondly, there is the life after germination. The conditions and the manner of life are not alike in the two stages. In the first the plant is heterotrophic, in the second it is autotrophic. The functions of the portion of the plant which lives the life within the seed, and which bears the incipient epicotyl and primary root as small, at times hardly developed, parts, are to absorb food, either before germination, as in exalbuminous seeds, or during germination in albuminous seeds, to rupture the seed-coat, and to place the plumular bud and the primary root in a satisfactory position for their growth and subsequent elongation. The functions of the adult may be summarised as the development and maintenance of a large assimilating and absorbing area preparatory to reproduction.

We ought, I think, to look upon the embryo as a protocorm[1] of embryonic tissue adapted to a seed-life. Under the influence of its heterotrophic nutrition and seed-environment it may develop organs not represented in the adult plant as we see in, for instance, the embryonal intraovular and extra-ovular haustoria it often possesses. There is no reason to assume that there must be homologies between the protocorm and the adult outside an axial part with its polarity. There may be homologous organs. But neither in ontogeny nor in phylogeny is there sufficient evidence to show that the parts of the embryo are a reduction of those of the adult.[2]

The protocorm has, I believe, developed along different lines in the Dicotyledones and Monocotyledones. This has been to the advantage of the former in the provision that has been made for rapid as opposed to sluggish further development. Confining ourselves to the general case, the axial portion of the protocorm of the Dicotyledon, the hypocotyl, bears a pair of lateral outgrowths, the cotyledons, and terminates in the plumular bud and in the primary root respectively. The cotyledons are its suctorial organs, and the hypocotyl does the work of rupturing the seed and placing the plumular bud and root by a rapid

[1] The anatomical characters upon which this resemblance was chiefly based are now known to be of another nature.

[1] The term has already been used for the embryo of Orchideæ, where the axis is tuberous as is the structure to which the term has been given in Lycopodineæ. But tuberousness is not an essential for the designation corm.

[2] I cannot pursue the subject here, nor discuss the view of the cotyledons as either ancestral leaf-forms or arrested epicotylar leaves. The analogies with existing Pteridophytes that are cited are not pertinent, for there is no evidence that Angiosperms have that ancestry, or indeed that their phylogeny was through forms with free embryos. Nor is the fact of resemblance between cotyledons and epicotylar leaves and the existence of transitions between them convincing. That the cotyledons, primarily suctorial organs, should change their function and become leaf-like under the new conditions after germination is no more peculiar than that the hypocotyl should take the form of an epicotylar internode, from which it is intrinsically different as the frequent development upon it of hypocotylar buds throughout its extent shows.

elongation[1] which commonly brings the plumular bud above ground, protected, it may be, by the cotyledons. These latter may then become the first assimilating organs unlike or like to the epicotylar leaves. In the Monocotyledones the axial portion of the protocorm has usually no suctorial outgrowths. Its apex and usually its base also are of limited growth. The plumular bud is a lateral development, and the primary root often an internal one. The suctorial function is performed by the apex of the protocorm, termed here also the cotyledon.[2] The rupture of the seed and the placing of the plumule along with the primary root—for the axis of the corm does not elongate between them—are the work of the base of the suctorial portion of the corm.

The whole arrangement in Monocotyledones is in marked contrast with that of the Dicotyledones. Instead of the free axial elongation begun in the protocorm and continued upwards and downwards in the epicotyl and primary root, there is limited axial growth of the protocorm with lateral outgrowth of the plumular bud and arrest of the primary root. These differences in the protocorm are, I think, primary, and they point to independent origins of the two groups. The advantage lies, as I have said, with the Dicotyledones, and we find that the features of development of the protocorm are continued in the adult. There is a marked contrast between the free internodal growth of the shoots of Dicotyledones with their copious root-system and the contracted stem-growth and the arrested root-system in Monocotyledones. It is interesting to note further how the monocotylous type has developed so largely upon restricted lines in the way of short rhizomatous, often tuberous, growth, whilst the dicotylous gives us the characteristic growth-form tree.

When we compare the tree-type of the Dicotyledones with that of the Monocotyledones we see at once the feature I refer to in the adult, which has given the advantage to the dicotylous type in respect of its water-supply. In Dicotyledones we have a much-branched stem ending with numerous shoots with long internodes and small apices, and bearing many small leaves which are mainly deciduous. In the monocotylous tree, of which we may take the palm as a type, there is a straight stem with short internodes, a large apex bearing few large leaves not often renewed; if there be branching it takes more or less the form of a fork. The whole of this external configuration bears relationship to the internal structure. In the Dicotyledon the open bundles of the central vascular system provide through their cambium for a continued increase of the water-carrying system and medullary rays, which, although it is to many a heresy, I hold to have profound influence upon the movement of water in trees. The buttressing of the branches is also secured, and thus is rendered possible a large assimilating area made up of a vast number of small individual surfaces, each one of which can be readily thrown off. In the Monocotyledones, on the other hand, the distribution of a large number of closed vascular bundles in a matrix without a cambium involves the provision of a broad terminal cone, gives no support, outside interstitial growth, to lateral branches, which are consequently when developed placed so as to give an equipose, and the assimilating surface has to be concentrated in a few large leaves. The possession of cambium has enabled the Dicotyledones to meet in a much better way the requirements of water-supply and strength in correlation with feeding.

The general uniformity and effectiveness of the scheme of cambial growth is a remarkable feature in the dicotylous type; but there is still a wide field of investigation in the relationships of size and distribution of vasa both to the other structural elements of the stem and to the form of the plant in relation to its environment. So far as I know the monocotylous tree-forms, there has been an attempt in two different directions to provide an increased water-carrying system in them. There is the familiar one of the secondary cortical cambium in Dracæna and other genera. In them the cambium merely repeats in its products the construction of the primary stem, and does not provide so copious an increase of carrying area as does the system in dicotylous plants. And then in such plants as Barbacenia, many Bromeliaceæ, perhaps Kingia, we have an arrangement reminiscent of the superficial root-system which is found in many polystelic arborescent Pteridophytes of the present day. There is a copious growth of adventitious roots from the central vascular cylinder, and these pass down within the cortex, and from its cells are no doubt able to draw water for the upper parts of the stem.[1] Ultimately many of these roots reach the soil. At best, however, neither of these systems has been satisfactory. All that can be said for them is that they have enabled the monocotylous trees in which they are found to hold their own in xerophilous conditions.

Of Phyla within Dicotyledones and Monocotyledones.

A brief reference only to the groups within the Dicotyledones and Monocotyledones must conclude these remarks. Whilst there is a wonderful concurrence in the opinion of botanists as to the natural groups—real phyla, whether termed cohorts, alliances, or series—into which many of the families of both Dicotyledones and Monocotyledones fall, there is irreconcilable divergence of view as to their genetic sequence or sequences. And this is not surprising when we remember that we know nothing of the starting point or points of the classes themselves; and have, moreover, no critical mark by which to diagnose a primitive from a reduced feature in many of the flower constructions to which, as characteristic of Angiosperms, importance is attached. The desire to establish a monophyletic sequence of these phyla is natural, and finds expression in pedigrees of Dicotyledones issuing from, it may be, Ranales or Piperales, of Monocotyledones from, say, Apocarpæ or Arales. But all such attempts appear to me, in the present state of our knowledge, to be in vain. We see in the phyla, as we know them, culminating series in our epoch in lines of descent; some, for instance Myrtales or Lamiales, progressive; others, like Primulales or Pandales, apparently not so. We also recognise that these series group themselves in many cases as branches of broader lines of descent; for example, in the Bicarpellatæ of Gamopetalæ, in the Helobieæ of Monocotyledones. To a greater or less degree such relationships are traceable now, and as we obtain more knowledge of the angiospermous plant-life of the world they will be widened. But this is a different thing from the carrying back the pedigree of every phylum of dicotylous and monocotylous plants to one or other of the existing ones, which may possess what are taken to be elementary characters. We have, so far as I know, no evidence to sanction the belief, or even the expectation, that there is extant any family of Dicotyledones or Monocotyledones which represents, even approximately, a primitive type in either class. The stem in each has gone. We have the twigs upon a few broken branches.

Amongst the phyla we cannot discern any one type that can be described as the dominant one. The multifarious adaptability of the angiospermous type has given us diverse forms, suited, as far as we discern, no less well to the varied environments of our epoch. Yet we are able to differentiate certain of them which take precedence alike in point of number of species and in area of distribution. If we seek for some general character that marks these advanced groups we find it in the tendency to greater investiture of the ovule, both in Dicotyledones and Monocotyledones. This is brought about in different ways; for instance, by the sinking of the gynæceum in the torus as in Compositæ, by inclusion within a persistent calyx as in Labiatæ, or within bracts as in Gramineæ. This feature, it will be observed, emphasises that which I have put in the forefront, as leading to the establishment of the angiospermous type. That it must give greater security to the embryo in relation to its water supply is obvious, although it has evidently also direct

[1] In relation to this function it is noteworthy that the hypocotyl relatively seldom in the exalbuminous seed of Dicotyledones becomes the reservoir of food-material, whereas in Monocotyledones the axis of the embryo is the usual seat of deposition.

[2] I use the term purely as an objective designation, and in the original meaning of the suctorial organ in the embryo. This terminal cotyledon in the Monocotyledones is not a leaf nor the homologue of the lateral cotyledones in the Dicotyledones. The "traceable and direct developmental history in the formation" of the two organs is clear, and they are not alike. To those who hold the contrary view a terminal leaf is no obstacle. I think, however, the question of lateral or terminal is of importance in organography. The "sympodial leaf-from-leaf evolution," described in the first epicotylar stages of Juncus, Pistia, and other plants, demands examination with the aid of modern methods. All cases of vegetative organs in which the distinctions between organs are said to break down are worthy of being looked at in the light of their relation to their nutritive environment. How nutrition affects plant-form we do not yet understand. Its effects are familiar, both in vegetative and reproductive organs. The grosser cases, in parasites, show in the extremes an abolition of most of the landmarks of morphology—"the whole scheme of formation of organs is jumbled." Heterotrophic "jumbles" do not, however, deny the ordinary morphological categories. Pseudo-terminal reproductive organs are to be expected under the cessation of growth with which their development is concurrent.

[1] I leave it to Palæophytologists to say whether this construction may sometimes account for the profusion of roots alongside of stem-structure in fossil-sections.

connection with seed-dispersal. Another general character observed in these higher groups is the greater security for economical pollination afforded by the adaptations in relation to insect-visits. At the same time the case of the Gramineæ shows us that other adaptations in this respect are not incompatible with prominence.

I will not dwell upon the influence of water upon the vegetative organs in Dicotyledones and Monocotyledones. Of all the factors of environment its effects are best known because most easily seen. The examination of plants from the standpoint of their relation to water—bearing in mind that this is physiological, and not merely physical—has already thrown a flood of light upon their forms and upon their distribution, and offers a fertile field of investigation for the future.

Water has been, then, a dominating influence at all periods in the evolution of our vegetation. The picture of its claim in this respect which I have presented to you is drawn in the broadest outline, and with the intention more of recalling points of view from which familiar facts in the life of plants may be looked at. It is just occasions like this which give the opportunity of telling to a competent audience of the impressions received by one's most recent glimpse in the kaleidoscope of plant-life. It is in this spirit I offer my imperfect sketch.

SECTION L.

EDUCATION.

Opening Address by the Right Hon. Sir John E. Gorst, F.R.S., President of the Section.

The invitation of the British Association to preside over the Section of Education, established this year for the first time, has been given to me as a representative of that Government Department which controls the larger, but perhaps not the most efficient, part of the education of the United Kingdom. The most suitable subject for my opening Address would therefore seem to be the proper function of National Authority, whether central or local, in the education of the people; what is the limit of its obligations; what is the part of Education in which it can lead the way; what is the region in which more powerful influences are at work, and in which it must take care not to hinder their operation; and what are the dangers to real education inseparable from a general national system. I shall avoid questions of the division of functions between Central and Local Authorities, beset with so many bitter controversies, which are political rather than educational.

In the first place, so far as the mass of the youth of a country is concerned, the Public Instructor can only play a secondary part in the most important part of the education of the young—the development of character. The character of a people is by far its most important attribute. It has a great deal more moment in the affairs of the world, and is a much more vital factor in the promotion of national power and influence, and in the spread of Empire, than either physical or mental endowments. The character of each generation depends in the main upon the character of the generation which precedes it; of other causes in operation the effect is comparatively small. A generation may be a little better or a little worse than its forefathers, but it cannot materially differ from them. Improvement and degeneracy are alike slow. The chief causes which produce formation of character are met with in the homes of the people. They are of great variety and mostly too subtle to be controlled. Religious belief, ideas, ineradicable often in maturer life, imbibed from the early instruction of parents, the principles of morality current amongst brothers and sisters and playmates, popular superstitions, national and local prejudices, have a far deeper and more permanent effect upon character than the instruction given in schools or colleges. The teacher, it is true, exercises his influence among the rest. Men and women of all sorts, from university professors to village dames, have stamped some part of their own character upon a large proportion of their disciples. But this is a power that must grow feebler as the number of scholars is increased. In the enormous schools and classes in which the public instruction of the greater part of the children of the people is given the influence on character of the individual teacher is reduced to a minimum. The old village dame might teach her half-dozen children to be kind and brave and to speak the truth, even if she failed to teach them to read and write. The head master of a school of 2000, or the teacher of a class of eighty, may be an incomparably better intellectual instructor, but it is impossible for him to exercise much individual influence over the great mass of his scholars.

There are, however, certain children for the formation of whose characters the nation is directly responsible—deserted children, destitute orphans, and children whose parents are criminals or paupers. It is the duty and interest of the nation to provide for the moral education of such children and to supply artificially the influences of individual care and love. The neglect of this obligation is as injurious to the public as to the children. Homes and schools are cheaper than prisons and workhouses. Such a practice as that of permitting dissolute pauper parents to remove their children from public control to spend the summer in vice and beggary at races and fairs, to be returned in the autumn, corrupt in body and mind, to spread disease and vice amongst other children of the State, would not be tolerated in a community intelligently alive to its own interest.

A profound, though indirect and untraceable, influence upon the moral education of a people is exercised by all national administration and legislation. Everything which tends to make the existing generation wiser, happier, or better has an indirect influence on the children. Better dwellings, unadulterated food, recreation grounds, temperance, sanitation, will all affect the character of the rising generation. Regulations for public instruction also influence character. A military spirit may be evoked by the kind of physical instruction given. Brutality may be developed by the sort of punishments enjoined or permitted. But all such causes have a comparatively slight effect upon national character, which is in the main the product for good or evil of more powerful causes which operate, not in the school, but in the home.

For the physical and mental development of children it is now admitted to be the interest and duty of a nation in its collective capacity to see that proper schools are provided in which a certain minimum of primary instruction should be free and compulsory for all, and, further, secondary instruction should be available for those fitted to profit by it. But there are differences of opinion as to the age at which primary instruction should begin and end; as to the subjects it should embrace; as to the qualifications which should entitle to further secondary instruction; and as to how far this should be free or how far paid for by the scholar or his parents.

The age at which school attendance should begin and end is in most countries determined by economic, rather than educational, considerations. Somebody must take charge of infants in order that mothers may be at leisure to work; the demand for child labour empties schools for older children. In the United Kingdom minding babies of three years old and upwards has become a national function. But the infant "school," as it is called, should be conducted as a nursery, not as a place of learning. The chief employment of the children should be play. No strain should be put on either muscle or brain. They should be treated with patient kindness, not beaten with canes. It is in the school for older children, to which admission should not be until seven years of age, that the work of serious instruction should begin, and that at first for not more than two or three hours a day. There is no worse mistake than to attempt by too early pressure to cure the evil of too early emancipation from school. Beyond the mechanical accomplishments of reading, writing, and ciphering, essential to any intellectual progress in after life, and dry facts of history and grammar, by which alone they are too often supplemented, it is for the interest of the community that other subjects should be taught. Some effort should be made to develop such faculties of mind and body as are latent in the scholars. The same system is not applicable to all; the school teaching should fit in with the life and surroundings of the child. Variety, not uniformity, should be the rule. Unfortunately, the various methods by which children's minds and bodies can be encouraged to grow and expand are still imperfectly understood by many of those who direct or impart public instruction. Examinations are still too often regarded as the best instrument for promoting mental progress; and a large proportion of the children in schools, both elementary and secondary, are not really educated at all—they are only prepared for examinations. The delicately expanding intellect is crammed with ill-understood and ill-digested facts, because it is the best way of preparing the scholar to undergo an Examination-test.

Learning to be used for gaining marks is stored in the mind by a mechanical effort of memory, and is forgotten as soon as the Class-list is published. Intellectual faculties of much greater importance than knowledge, however extensive—as useful to the child whose schooling will cease at fourteen as to the child for whom elementary instruction is but the first step in the ladder of learning—are almost wholly neglected.

The power of research—the art of acquiring information for oneself—on which the most advanced science depends, may by a proper system be cultivated in the youngest scholar of the most elementary school. Curiosity and the desire to find out the reason of things is a natural, and to the ignorant an inconvenient, propensity of almost every child; and there lies before the instructor the whole realm of Nature knowledge in which this propensity can be cultivated. If children in village schools spent less of their early youth in learning mechanically to read, write, and cipher, and more in searching hedgerows and ditch-bottoms for flowers, insects, or other natural objects, their intelligence would be developed by active research, and they would better learn to read, write, and cipher in the end. The faculty of finding out things for oneself is one of the most valuable with which a child can be endowed. There is hardly a calling or business in life in which it is not better to know how to search out information than to possess it already stored. Everything, moreover, which is discovered sticks in the memory and becomes a more secure possession for life than facts lazily imbibed from books and lectures. The faculty of turning to practical uses knowledge possessed might be more cultivated in Primary Schools. It can to a limited extent, but to a limited extent only, be tested by examination. Essays, compositions, problems in mathematics and science, call forth the power of using acquired knowledge. Mere acquisition of knowledge does not necessarily confer the power to make use of it. In actual life a very scanty store of knowledge, coupled with the capacity to apply it adroitly, is of more value than boundless information which the possessor cannot turn to practical use. Some measures should be taken to cultivate taste in Primary Schools. Children are keen admirers. They can be early taught to look for and appreciate what is beautiful in drawing and painting, in poetry and music, in Nature, and in life and character. The effect of such learning on manners has been observed from remote antiquity.

Physical exercises are a proper subject for Primary Schools, especially in the artificial life led by children in great cities: both those which develop chests and limbs, atrophied by impure air and the want of healthy games, and those which discipline the hand and the eye—the latter to perceive and appreciate more of what is seen, the former to obey more readily and exactly the impulses of the will. Advantage should be taken of the fact that the children come daily under the observation of a quasi-public officer—the school teacher—to secure them protection, to which they are already entitled by law, against hunger, nakedness, dirt, over-work, and other kinds of cruelty and neglect. Children's ailments and diseases should by periodic inspection be detected: the milder ones, such as sores and chilblains, treated on the spot, the more serious removed to the care of parents or hospitals. Diseases of the eye and all maladies that would impair the capacity of a child to earn its living should in the interest of the community receive prompt attention and the most skilful treatment available. Special schools for children who are crippled, blind, deaf, feeble-minded, or otherwise afflicted should be provided at the public cost, from motives, not of mere philanthropy, but of enlightened self-interest. So far as they improve the capacity of such children they lighten the burden on the community.

I make no apology for having dwelt thus long upon the necessity of a sound system of primary instruction: that is the only foundation upon which a national system of advanced education can be built. Without it our efforts and our money will be thrown away. But while primary instruction should be provided for, and even enforced upon, all, advanced instruction is for the few. It is the interest of the commonwealth at large that every boy and girl showing capacities above the average should be caught and given the best opportunities for developing those capacities. It is not its interest to scatter broadcast a huge system of higher instruction for anyone who chooses to take advantage of it, however unfit to receive it. Such a course is a waste of public resources. The broadcast education is necessarily of an inferior character, as the expenditure which public opinion will at present sanction is only sufficient to provide education of a really high calibre for those whose ultimate attainments will repay the nation for its outlay on their instruction. It is essential that these few should not belong to one class or caste, but should be selected from the mass of the people, and be really the intellectual *élite* of the rising generation. It must, however, be confessed that the arrangements for selecting these choice scholars to whom it is remunerative for the community to give advanced instruction are most imperfect. No "capacity-catching machine" has been invented which does not perform its function most imperfectly: it lets go some it ought to keep, and it keeps some it ought to let go. Competitive examination, besides spoiling more or less the education of all the competitors, fails to pick out those capable of the greatest development. It is the smartest, who are also sometimes the shallowest, who succeed. "Whoever thinks in an examination," an eminent Cambridge tutor used to say, "is lost." Nor is position in class obtained by early progress in learning an infallible guide. The dunce of the school sometimes becomes the profound thinker of later life. Some of the most brilliant geniuses in art and science have only developed in manhood. They would never in their boyhood have gained a county scholarship in a competitive examination.

In Primary Schools, while minor varieties are admissible, those, for instance, between town and country, the public instruction provided is mainly of one type; but any useful scheme of higher education must embrace a great variety of methods and courses of instruction. There are roughly at the outset two main divisions of higher education—the one directed to the pursuit of knowledge for its own sake, of which the practical result cannot yet be foreseen, whereby the "scholar" and the votary of pure science is evolved; the other directed to the acquisition and application of special knowledge by which the craftsman, the designer, and the teacher are produced. The former of these is called Secondary, the latter Technical, Education. Both have numerous subdivisions which trend in special directions.

The varieties of secondary education in the former of these main divisions would have to be determined generally by considerations of age. There must be different courses of study for those whose education is to terminate at sixteen, at eighteen, and at twenty-two or twenty-three. Within each of these divisions, also, there would be at least two types of instruction, mainly according as the student devoted himself chiefly to literature and language, or to mathematics and science. But a general characteristic of all Secondary Schools is that their express aim is much more individual than that of the Primary School: it is to develop the potential capacity of each individual scholar to the highest point, rather than to give, as does the Elementary School, much the same modicum to all. For these reasons it it essential to have small classes, a highly educated staff, and methods of instruction very different from those of the Primary School. In the formation of character the old Secondary Schools of Great Britain have held their own with any in the world. In the rapid development of new Secondary Schools in our cities it is most desirable that this great tradition of British Public School life should be introduced and maintained. It is not unscientific to conclude that the special gift of colonising and administering dependencies, so characteristic of the people of the United Kingdom, is the result of that system of self-government to which every boy in our higher Public Schools is early initiated. But while we boast of the excellence of our higher schools on the character-forming side of their work, we must frankly admit that there is room for improvement on their intellectual side. Classics and mathematics have engrossed too large a share of attention; science, as part of a general liberal education, has been but recently admitted, and is still imperfectly estimated. Too little time is devoted to it as a school subject: its investigations and its results are misunderstood and undervalued. Tradition in most schools, nearly always literary, alters slowly, and the revolutionary methods of science find all the prejudices of antiquity arrayed against them. Even in scientific studies, lack of time and the obligation to prepare scholars to pass examinations cause too much attention to be paid to theory, and too little to practice, though it is by the latter that the power of original research and of original application of acquired knowledge is best brought out. The acquisition of modern languages was in bygone generations almost entirely neglected. In many schools the time given to this subject is still inadequate, the method of teaching antiquated, the results unsatisfactory. But the absolute necessity of such knowledge in literature, in science, and in commerce is already producing a most salutary reform.

The variety of types of secondary instruction demanded by the various needs and prospects of scholars requires a corresponding variety in the provision of schools. This cannot be settled by a rule-of-three method, as is done in the case of primary instruction. We cannot say that such and such an area being of such a size and of such a population requires so many secondary schools of such a capacity. Account must be taken in every place of the respective demands for respective types and grades of secondary education; and existing provision must be considered.

It must not, however, be forgotten that a national system of education has its drawbacks as well as its advantages. The most fatal danger is the tendency of public instruction to suppress or absorb all other agencies, however long established, however excellent their work, and to substitute one uniform mechanical system, destructive alike to present life and future progress. In our country, where there are public schools of the highest repute carried on for the most part under ancient endowments, private schools of individuals and associations, and Universities entirely independent of the Government, there is reasonable hope that with proper care this peril may be escaped. But its existence should never be forgotten. Universal efficiency in all establishments that profess to educate any section of the people may properly be required; but the variety, the individuality, and the independence of schools of every sort, primary and secondary, higher and lower, should be jealously guarded. Such attributes once lost can never be restored.

There still remains for our consideration the second division of Higher Education, viz., the applied or technological side. It is in this branch of Education that Great Britain is most behind the rest of the world; and the nation in its efforts to make up the lost ground fails to recognise the fact that real technical instruction (of whatever type) cannot possibly be assimilated by a student unless a proper foundation has been laid previously by a thorough grounding of elementary and secondary instruction. Our efforts at reform are abrupt and disconnected. A panic from time to time sets in as to our backwardness in some particular branch of commerce or industry. There is a sudden rush to supply the need. Classes and schools spring up like mushrooms, which profess to give instruction in the lacking branch of applied science to scholars who have no elementary knowledge of the particular science, and whose general capacities have never been sufficiently developed. Students are invited to climb the higher rungs of the ladder of learning who have never trod the lower. But science cannot be taught to those who cannot read, nor commerce to those who cannot write. A few elementary lessons in shorthand and book-keeping will not fit the British people to compete with the commercial enterprise of Germany. Such sudden and random attempts to reform our system of technical education are time and money wasted. There are grades and types in technological instruction, and progress can only be slow. It is useless to accept in the higher branches a student who does not come with a solid foundation on which to build. In such institutions as the Polytechnics at Zurich and Charlottenburg we find the students exclusively drawn from those who have already completed the highest branches of general education; in this country there is hardly a single institution where this could be said of more than a mere fraction of its students. The middle grades of technological instruction suffer from a similar defect. Boys are entered at technical institutions whose only previous instruction has been at elementary schools and evening classes; whose intellectual faculties have not been developed to the requisite point; and who have to be retaught the elements to fit them for the higher instruction. In fact there is no scientific conception of what this kind of instruction is to accomplish, and of its proper and necessary basis of general education.

Yet this is just the division of higher education in which public authority finds a field for its operations practically unoccupied. There are no ancient institutions which there is risk of supplanting. The variety of the subject itself is such that there is little danger of sinking into a uniform and mechanical system. What is required is first a scientific, well-thought-out plan and then its prompt and effective execution. A proper provision of the various grades and types of technological instruction should be organised in every place. The aim of each institution should be clear; and the intellectual equipment essential for admission to each should be laid down and enforced. The principles of true economy, from the national point of view, must not be lost sight of. Provision can only be made (since it must be of the highest type to be of the slightest use) for those really qualified to profit by it to the point of benefiting the community. Evening classes with no standard for admission and no test of efficiency may be valuable from a social point of view as providing innocent occupation and amusement, but they are doing little to raise the technical capacity of the nation. So far from "developing a popular demand for higher instruction" they may be preventing its proper growth by perpetuating the popular misconception of what real technical instruction is, and of the sacrifices we must make if our people are to compete on equal terms with other nations in the commerce of the world. The progress made under such a system would at first be slow; the number of students would be few until improvements in our systems of primary and secondary instruction afforded more abundant material on which to work; but our foundation would be on a rock, and every addition we were able to make would be permanent, and contribute to the final completion of the edifice.

It is the special function of the British Association to inculcate "a scientific view of things" in every department of life. There is nothing in which scientific conception is at the present moment more urgently required than in National Education; and there is this peculiar difficulty in the problem, that any attempt to construct a national system inevitably arouses burning controversies, economical, religious, and political. It is only a society like this, with an established philosophical character, that can afford to reduce popular cries about education (which ignore what education really is, and perpetuate the absurdity that it consists in attending classes, passing examinations, and obtaining certificates) to their true proportions. If this Association could succeed in establishing in the minds of the people a scientific conception of a National Education System, such as has already been evolved by most of the nations of Europe, the States of America, and our own Colonies, it would have rendered a service of inestimable value to the British nation.

GEOLOGY AT THE BRITISH ASSOCIATION.

An arduous week's work was carried out in the Section of Geology at Glasgow. There was a full list of papers—in fact, too full for adequate discussion of all—ranging widely over the whole group of sciences combined under the name of geology. While stratigraphical papers were, as usual, in the ascendancy, petrology and palæontology were both strongly represented, mineralogy (with crystallography), of late years somewhat neglected in this Section, counted several contributions, and matters of physical and economic geology received attention in others. Many of the papers were admirably adapted for initiating discussion, and in some instances fulfilled this purpose, though, as generally happens with a heavy list, the discussions were somewhat unequally distributed. It might, perhaps, be said of many of the papers that they were instructive summaries of what was already known rather than new additions to our knowledge. The general arrangement was that the papers dealing with Scottish geology were taken as far as possible on Thursday and Friday, Saturday was given up to excursions, palæontological subjects occupied most of the Monday sitting, mineralogical papers were given precedence on Tuesday, and the concluding session on Wednesday served for the postponed or unclassified contributions. In the following outline of the proceedings of the Section we shall not have space to mention all the papers which were read, and must content ourselves with brief mention of those which seemed to us to be of chief interest.

After the president's address on Thursday, already printed in our columns, a paper on recent discoveries in Arran geology, by Mr. W. Gunn, of H.M. Geological Survey, read by Mr. Peach, gave a general summary of recent important advances in our knowledge of the island. Among its older rocks a series of dark schists and chert, unfossiliferous but probably of Arenig age, have been discovered; the Old Red Sandstone has been found to comprise two subdivisions, of which the upper is unconformable on the lower; the Carboniferous, including beds probably of Coal Measure age, are overlapped unconformably by the New Red rocks, the latter consisting of sandstones, conglomerates and marls which seem to be of Triassic age.

Fragments of Rhætic, Liassic and Cretaceous rocks which must once have covered the area have been recognised by their fossils in a large volcanic vent; this volcano was probably of Tertiary age, to which period are also assigned most of the igneous rocks, though six earlier periods of volcanic activity have been now recognised in this most interesting island.

Mr. G. Barrow followed with a suggestive paper on lateral variations of composition in zones of the Eastern Highland schists, which he ascribed to original variation in the sediments deposited in a delta. Mr. P. Macnair then gave his interpretation of the structure and probable succession of the schists of the Southern Highlands, which he considers to form an ascending sequence in the following order: Lower Argillaceous zone, Lower Arenaceous zone, Loch Tay Limestone, Garnetiferous schist, Upper Argillaceous zone and Upper Arenaceous zone.

The differentation of a rock-magma was well illustrated by Prof. J. Geikie and Dr. J. S. Flett in their description of the granite of Tulloch Burn, Ayrshire, which passes at its margins into intermediate and basic rocks.

The occurrence of a phosphatic layer at the base of the Inferior Oolite in Skye, lining a hollow of local erosion in the Upper Lias shales, was briefly described in a paper by Mr. H. B. Woodward.

On Friday the first paper was a lucid account by Sir Arch. Geikie of the re-discovery of a tree-trunk embedded in volcanic ash in Mull. This tree was described long ago by Macculloch, but occurs in a sea-cliff very difficult of access, and received no further notice until visited recently by Sir Arch. Geikie. The stump is about 5 feet in diameter and 5 feet high, and must have belonged to a tree originally at least 80 feet high. It is of peculiar interest in showing that time-intervals of quiescence of considerable length occurred between separate volcanic outbursts.

Another notable contribution to Scottish volcanic geology was made by Mr. A. Harker in a paper on the sequence of the Tertiary igneous eruptions in Skye, read by Dr. Flett in the absence of the author. As the result of his detailed mapping of the volcanic rocks of Skye for the Geological Survey, Mr. Harker finds that he can recognise three successive phases of igneous activity—the *volcanic*, the *plutonic*, and the phase of *minor intrusions*. He further distinguishes two parallel series of events—the *regional* and the *local*, the former of very wide extension, the latter connected with certain definite foci, one of which was situated in Central Skye.

The *regional* eruptive rocks are all of basic composition, but the *local* groups exhibit much greater diversity. During the plutonic phase the successive groups of intrusions at the Skye centre followed an order of increasing acidity; but for the local groups of the succeeding phase of minor intrusions this order was reversed. Mr. Harker suggests that this sequence of Tertiary igneous eruptions may probably be taken as a type of the whole British area; and we may be sure that all students of these difficult rocks will await with impatience the publication of the detailed observations on which Mr. Harker's far-reaching generalisations are based.

Two papers by Messrs. A. McHenry and J. R. Kilroe, of the Irish branch of the Geological Survey, dealing with the older rocks of the north-west of Ireland and their bearing on Scottish geology, were next read. In the first the authors called attention to the close resemblance of the Old Red Sandstone of north-west Ireland to the Torridon rocks of Sutherland both in composition and structural relationships, and suggested that the Torridon rocks were therefore really of Old Red age. This paper gave rise to an animated discussion, in which Profs. Sollas, Lapworth and Hull, Messrs. Peach, Barrow, Greenly, Goodchild, Caddell, Hinxman, Craig and the President took part. The consensus of opinion was that the suggested new reading of the Torridon succession could not be sustained; and one of the speakers aptly proposed that as the question had been well-threshed out, an abstract of the discussion should be printed as a permanent record of the evidence for the age of the Scottish Torridonian.

Messrs. Kilroe and McHenry's second paper dealt with the relation of the Silurian and Ordovician rocks of north-west Ireland to the Great Metamorphic Series, their contention being that the latter consisted of metamorphosed Lower Silurian sediments and associated intrusions, over which the unmetamorphosed rocks were carried by overfolding and great dislocations in Llandovery times. In the next paper on the list, by Mr. G. H. Kinahan, this view was controverted, and the earlier age of the metamorphic series upheld, these being compared with the Algonkian of North America.

Dr. Traquair then gave interesting lantern demonstrations on the geological distribution of the fishes of the Carboniferous rocks and of the Old Red Sandstone of Scotland. The study of the Carboniferous fish-faunas led to the conclusion that the rocks were divisible into two parts—Upper and Lower Carboniferous, with a great break at the base of the Millstone Grit, the Upper Carboniferous fauna being like that of England, and that of the Lower Carboniferous differing only where fresh-water or estuarine conditions displaced the marine forms. At a later session similar results were presented by Mr. R. Kidston in his description of fossil plants from Berwickshire.

In the concluding papers on Friday the Section was carried far afield by Miss C. A. Raisin in her account of the volcanic rocks of Perim Island, and by Dr. R. Logan Jack in his description of the conditions under which enormous supplies of artesian water are obtained in Queensland, where borings of the aggregate length of 185 miles have been made with incalculable advantage to the country, as the result of geological investigations in which Dr. Jack was a pioneer. The deepest of these borings attained the exceptional depth of 5045 feet.

On Monday, when precedence was given to palæontological papers, Mr. B. N. Peach came first with an admirable *résumé* of our knowledge of the Cambrian fossils of the North-West Highlands, in which stress was laid on the close agreement between the Scottish and North American fossil zones of this ancient period, betokening a shore-line connection between the continents, with a deep-water barrier to the southward, separating the north of Scotland from the mid-European and Welsh areas.

Prof. Sollas then exhibited and explained his machine for investigating fossil-remains. By Prof. Sollas's method the fossil is ground down slowly, and a series of parallel sections obtained from which it is easy to construct a model of the whole fossil. The great value of this machine as an instrument of research was demonstrated by a series of lantern slides and by wax models.

Mr. A. M. Bell gave an account of the plants and coleoptera from a Pleistocene deposit at Wolvercote, Oxfordshire; the plants indicated a more continental climate of the Thames valley during the period than at present, and a later date for the deposit than the Hoxne beds.

Papers on glacial geology were fewer than of late years, and indeed, with the exception of the Report of the Erratic Blocks Committee, the only strictly glacial paper was that of Prof. P. F. Kendall and H. B. Muff on overflow channels and other phenomena indicating glacier-dammed lakes in the Cheviots, in which region these observers have recently recognised similar phenomena to those which they had previously investigated in Yorkshire.

The application of geology to agriculture by the preparation of soil maps was the subject of a communication by Mr. J. R. Kilroe, who exhibited a specimen-map, on which the general character of the soil was indicated by a few colours selected from those of our usual geological maps, but intended to show the soil-characters only, without particular reference to the geological structure.

Tuesday was primarily the mineralogists' day, and the session was opened by Mr. J. G. Goodchild with a paper on the Scottish ores of copper in their geological relations, in which these ores were classed into two primary categories, those of the first being assigned to the uprise of thermal waters, and of the second to solutions passing downwards from higher to lower levels. The same author, in another communication, dealt with a revised list of Scottish minerals, and indicated its more salient points. Dr. W. Mackie followed with a series of three papers on the Trias of Elgin and Nairn, one describing the occurrence of barium sulphate and calcium fluoride as cementing substances in the Elgin area, believed by the author to have been directly deposited during the concentration of the waters of an inland lake; another recording covellite and malachite in a vein in the sandstone of Kingsteps, Nairn; and the third, on which there was an excellent discussion, on the pebble-band of the Elgin Trias, which was shown to be of wider extent than hitherto supposed and to mark a definite horizon at the base of the Trias, the overlying Cutties Hillock sandstones being really made up of Triassic sand-dunes, while in the pebble-bed many of the stones present characters showing them to have been wind-worn. At this point we may also mention a mineralogical paper by Dr. J. S. Flett, read at an earlier session, on crystals dredged from the Clyde near Helensburgh, which are believed to be pseudomorphs after celestine.

In a paper on the source of the alluvial gold of the Kildonan field, Sutherland, Mr. J. Malcolm Maclaren, as the result of a recent investigation, concludes that the gold has been derived from the white quartz veins of the local schists, whence it has been distributed into the glacial-drift and finally concentrated mechanically in the present stream-courses. In a second paper Mr. Maclaren dealt with the influence of organic matter on the deposition of gold in veins, from personal observation on the reefs of the Sympic and Croydon goldfields of Queensland and of the Ballarat field of Victoria, giving illustrations of the enrichment of the veins at the contact with carbonaceous or graphitic rocks, and suggesting the possibility of precipitation by carbonaceous matter, in accordance with the opinion once generally held, but latterly much discredited.

Mr. E. H. Cunningham Craig described the mode of occurrence of cairngorms, the search for which was formerly a profitable Scottish industry, but has now been practically abandoned. These idiomorphic quartz-crystals occur in the drusy central zones of veins of fine-grained granite traversing the normal coarser and less acid granites.

Prof. Joly's computations of the age of the earth from the amount of salt in the sea were incidentally criticised by Mr. W. Ackroyd in a paper on the circulation of salt and its geological bearings. It was shown by Mr. Ackroyd that for the Millstone Grit and limestone districts of Yorkshire, as well as for a belt of the American coast some 200 miles broad, fully 99 per cent. of the salt carried by the rivers was cyclic sea-salt which had been atmospherically transported and carried down by rain, while Prof. Joly allows only 10 per cent. as the proportion thus derived in our rivers. Reference was made to estimates by the author that during 1900–1901 the deposition of salt derived from the sea amounted to 172·3 lbs. per acre per year on the Pennine Hills at over 1000 feet above sea-level.

At the same session Mr. W. H. Wheeler discussed the sources of the warp in the Humber, urging that the material was brought down by the rivers flowing into the Humber, and not by the inflowing tide from the waste of the Holderness coast as has been authoritatively stated. Two papers by Mr. J. Rhodes were also read, describing the discovery of phosphatic nodules and phosphate-bearing rock in the Upper Carboniferous Limestone series on the Yorkshire and Westmorland border, and of a silicified plant seam in the same locality.

There still remained a list of ten papers and reports to be taken at the final meeting on Wednesday, the majority being papers dealing with foreign geology. Dr. A. Smith Woodward sent an account of his recent investigations of the famous bone-beds of Pikermi, Attica, where in re-working the old locality he obtained fragmentary evidence of a gigantic tortoise at least as large as the largest hitherto found in Europe, and in a new locality, at Achmet Aga in North Eubœa, sixty miles distant from the former, he found a similar bone-bed, probably formed in like manner by torrential floods carrying down their débris into lakes.

Mr. H. J. L. Beadnell, of the Geological Survey of Egypt, also sent an account of the discovery of bone-beds of early Tertiary age in the Fayum depression, which have yielded many new mammalian and reptilian remains now being worked out by Dr. C. W. Andrews, of the British Museum, who visited the locality with Mr. Beadnell.

Prof. E. Hull, in continuance of his researches on submarine physiography, discussed the physical history of the Norwegian fjords. These he believes to be essentially river-valleys, of which the lower portions, probably once deep gorges traversing what is now the open sea-floor, are entirely filled with drift, and thus obliterated.

The origin of the gravel flats of Surrey and Berkshire was discussed by Mr. H. W. Monckton, who concludes that these deposits were river-gravels formed since the country last rose above the sea, during periods of repose in the process of elevation, which was differential in its effects.

As usual, much of the best work brought before the Section was embodied in the Reports of Committees of Research, for which, unfortunately, we have barely space for mention. The report of the Geological Photographs Committee, by Prof. W. W. Watts, and that on Erratic Blocks, by Prof. P. F. Kendall, showed the same substantial progress which these vigorous committees customarily present. The report on Carboniferous Life-zones, by Dr. Wheelton Hind, and that on the Underground Waters of N.W. Yorkshire, by Captain A. R. Dwerryhouse, though hampered by unforeseen local difficulties in the latter case, also showed solid progress; while that on the Exploration of Irish Caves gave a preliminary account of the good results attained by the first year's working at Keish, co. Sligo; and that on the Structure of Crystals (drawn up by Mr. W. Barlow and Prof. H. A. Miers, assisted by Mr. G. F. Herbert Smith) forms an invaluable contribution to the history of crystallographic research.

As usual there were afternoon excursions during the meeting to places of geological interest within easy reach of Glasgow, besides the whole-day excursions to Girvan, Arran, Loch Lomond and The Trossachs on Saturday. The attendance at the sectional meetings throughout was quite up to the average of recent years, and general satisfaction was expressed with the character of the proceedings of Section C at Glasgow.

ZOOLOGY OF THE TWENTIETH CENTURY.[1]

WE have stood in retrospect at the close of the nineteenth century and marvelled at what it brought forth. Here at the threshold of the twentieth century it is natural that we should wonder what it will unfold. Will the changes be as great and in what direction will advance chiefly be made? I am the more content to consider such questions for three reasons: first, because we can use history to formulate predictions; second, because the attempt may possibly influence to some slight degree the future development of zoology; and third, because the attempt is tolerably safe since we shall none of us know all that the century will bring forth.

Comparing the beginning of the twentieth century with that of the nineteenth we find the most striking advances to have taken place in our morphological knowledge. The nineteenth may, indeed, be designated the morphological century. The demands of systematic zoology first made anatomical studies necessary. Later, comparison came to be accepted as the fundamental zoological method, and comparative anatomy, emancipated from its servitude to systematic zoology, became an independent science. Still later embryology arose, at first as a descriptive science and then as a comparative one. Out of embryology arose modern cytology, which in turn is creating a comparative histology. Partly as a result of studying embryology as a process has arisen the modern tendency toward comparative physiology. As a result of the general acceptance of the evolution doctrine the study of the geographical distribution of organisms and of adaptations has gained a new meaning. From the great matrix of "general biology" there have begun to crystallise out a number of well-defined subsciences.

Looking broadly at the progress made during the past century we see that zoology has become immensely more complex due to its developing in many lines, and that the new lines are largely interpolated between the old and serve to connect them. The descriptive method has developed into a higher type—the comparative; and of late years still a new method has been introduced for the study of processes—the experimental. The search for mechanisms and causes has been added to the search for the more evident phenomena. The zoologist is no longer content to collect data; he must interpret them.

In view of the past history of our science what can we say of its probable future? We may be sure that zoology will develop in all these three directions: (1) The continued study of old subjects by old methods; (2) the introduction of new methods of studying old subjects; and (3) the development of new subjects.

I am not of those who would belittle the old subjects, even when pursued in the old way. There is only one class of zoologist that I would wish to blot out, and that is the class whose reckless naming of new "species" and "varieties" serves only to extend the work and the tables of the conscientious synonymy hunter. Other than this all classes will contribute to the advancement of the science. No doubt there are unlabled species and no doubt they must, as things are, be named. And no doubt genera and families must be "revised" and some groups split up and others lumped. So welcome to the old-fashioned systematist, though his day be short, and may

[1] Address delivered before the Section of Zoology of the American Association for the Advancement of Science, at Denver, by Prof. C. B. Davenport, president of the Section

he treat established genera gently. No doubt there are types of animals of whose structure we are woefully ignorant; no doubt we need to know their internal anatomy in great detail. So welcome to the zootomist in this new century, and may he invent fewer long names for new organs. No doubt there are groups of whose relationships we know little, and which have been buffeted about from one class to another in a bewildering way. We need to have their places fixed. So welcome to the comparative anatomist and the embryologist, and may their judgment as to the relative value of the criteria of homology grow clearer. No doubt our knowledge of inheritance and development will be immensely advanced by the further study of centrosomes, asters and chromosomes. Welcome, therefore, to the cytologist, and may he learn to distinguish coagulation products and plasmolytic changes from natural structures. All these subjects have victories in store for them in the new century. To neglect them is to neglect the foundations of zoology.

But the coming century will, I predict, see a change in the methods of studying many of these subjects. In systematic zoology fine distinctions will no longer be expressed by the rough language of adjectives, but quantitatively, as a result of measurement. There is every reason to expect, indeed, that the future systematic work will look less like a dictionary and more like a table of logarithms. Our system of nomenclature, meanwhile, will probably break down from its own weight. Now that the binomial system of nomenclature has been replaced by a trinomial, there is no reason why we should not have a quadrinomial nomenclature or even worse. It seems as if the Linnæan system of nomenclature is doomed. What will take its place can hardly be predicted. The new system should recognise the facts of place-modes and colour-varieties. We might establish certain categories of variation such as those of geographical regions, of habitat, of colour. A decimal system of numbers might be applied to the parts of the country or the kinds of habitat and the proper number might take the place of the varietal or subvarietal name. Thus the north-eastern skunk might be designated *Mephitis mephitica* 74, and the south-eastern skunk *Mephitis mephitica* 75 (adopting the Dewey system of numerals). The Maine skunk would then be 741, that of New York 747, and so on. This much for a suggestion.

So likewise for the morphologist the coming century will bring new aims and new methods. No longer will the construction of phylogenetic trees be the chief end of his studies, but a broad understanding of the form producing and the form maintaining processes. The morphologist will more and more consider experiment a legitimate method for him. The experimental method will, I take it, be extended especially to the details of cytology, and here cytology will make some of its greatest advances.

Not only will the old subjects be studied by new methods, but we have every reason to believe that new subsciences will arise during the twentieth century as they arose during the nineteenth. Of course we cannot forecast all of these unborn sciences, as cytology and neurology could hardly have been forecast at the beginning of the nineteenth century. But we can see the beginnings of what are doubtless to be distinct sciences. Thus comparative physiology is still in its infancy, and is as yet hardly worthy of the name of a science; there is no question that this will develop in the coming decades. Animal behaviour has long been treated in a desultory way, and many treatises on the subject are rather contributions to folk-lore than to science. But we are beginning to see a new era—an era of precise, critical and objective observation and record of the instincts and reactions of animals. One day we shall reach the stage of comparative studies and shall have a science of the ontogeny of animal instincts. This will have the same importance for an interpretation of human behaviour that comparative anatomy and embryology have for human structure.

Prominent among the advances of the century will be the ability to control biological processes. We shall know the factors that determine the rate of growth and the size of an animal, the direction and sequence of cell-divisions, the colour, sex and details of form of a species. The direction of ontogeny and of phylogeny will be to a greater or less extent under our control.

The study of animals in relation to their environment, long the pastime of country gentlemen of leisure, will become a science. Some day we shall be able to say just what determines an animal's presence at any place; and, more than that, we shall be able to account for the fauna, the sum total of animal life of any locality, and to trace the history of that fauna. This is at least one of the aims of animal ecology. It is a reproach to zoology that the subject of animal ecology should lag so far behind that of plant ecology. When zoologists fully awaken to a realisation of what a fallow field lies here this reproach will quickly be wiped out. As it is we have a notion that the factors determining the occurrence of an animal or of a fauna are too complicated to be unravelled. As a matter of fact the factors are often quite simple. Let me illustrate this by some studies I have made this summer on the Cold Spring Beach. This beach is a spit of sand 2000 feet long and 50 to 75 feet broad, running from the western mainland into the harbour and ending in a point that is being made several feet a year through the cooperation of wave, tide, and a silt-transporting creek of fresh water. On the outer harbour side is a broad, gradually sloping sandy and gravelly beach, covered by high tide, and devoid of living vegetation. Above that is a narrow zone—the middle beach—covered with the débris of storms, supporting a few annual plants, and bounded above by a storm-cut bluff. Above is the upper beach, covered with a perennial, sand-loving vegetation. On the lower beach the zonal distribution of animals is striking. Just above the water are found the scavenger mud-snails, and, further up, a crowd of Thysanura—small insects that rise to the surface of the water when the tide comes in. These find a living on the finer débris or silt that settles on the pebbles during the high tides. In this zone also Limulus lays its eggs in the sand, and its nests are crowded with nematodes that feed on the eggs. During the breeding season scores of the female Limulus die here, and their carcasses determine a complex fauna. First, carrion beetles (Necrophorus) and the flesh fly live on the dead bodies; then the robber flies and tiger-beetles are here to feed on this fauna, and, finally, numerous swallows course back and forth, gleaning from this rich field. At the upper edge of the lower beach is a band of débris dropped at slack water and consisting especially of shreds of Ulva and many drowned insects, especially beetles. At this zone or just above, under the drier but more abundant wreckage of the last storm, occur numerous Amphipoda of the genera Orchestia and Talorchestia. Associated with these marine creatures are numerous red ants, sand-coloured spiders and rove-beetles. The amphipods feed on the decaying sea-weed. The ants are here looking chiefly for the drowned insects. Their nests are further up on the middle beach, but the workers travel to the edge of the high tide to bring away their booty. The rove-beetles are general scavengers. The spiders, which are mostly of the jumping sort (of the family Attidæ), feed on the active insects and amphipods. At a higher zone and above all but the storm-driven tides one finds the nests of the ants, especially under logs, certain predaceous beetles and the xerophilous grasshoppers and crickets. Finally, on the plant-covered upper beach one finds characteristic leaf-eating beetles, grasshoppers and carnivorous insects. Now all this seems commonplace enough and not especially instructive, and yet if you go to the shore of Lake Michigan you will find on a similar beach closely similar, if not identical, forms (excepting the beach fleas and the horse-shoe crabs); you will find similar ants, spiders, rove-beetles, tiger-beetles and sand grasshoppers. This fact alone shows the greater importance of habitat over geographical region in determining the assemblage of animals that occurs in any one place. It may be predicted that studies on the relation of animals to their habitat will multiply, that they will become comparative and that the science of animal ecology will become recognised as no less worthy and no less scientific than the science of morphology.

Studies on the origin of species were far from being unknown in the nineteenth century, but they were for the most part fragmentary or speculative or narrow in view. The opinion that there was one method of evolution seemed to hold sway. It seems to me that the signs of the times indicate that we are about to enter upon a thorough, many-sided, inductive study of this great problem, and that there is a willingness to admit that evolution has advanced in many ways. The attempt, therefore, to explain all specific peculiarities on the ground of natural selection, or on the ground of self-adjustment, or on the ground of sport-preservation through isolation we may expect equally to prove futile. All these causes are no doubt real in some cases, but to exclude any one or to deny that new causes may be found in the future is equally dangerous and unscientific.

It is often said that the factors of evolution are inheritance and variation. In the new century careful and quantitative studies will be made on these factors. We shall get at quantitative expressions of the more complicated forms of heritage in the same way as Galton has given us an expression of a simple form of inheritance. We shall hope to understand why some qualities blend and others refuse to do so. We shall learn the laws of mingling of qualities in hybrids and get an explanation of the monstrosities and the sterility which accompany hybridisation. What we call reversion and prepotency will acquire a cytological explanation, and it may be that the theory of fertilisation will be seriously modified thereby. When we can predict the outcome of any new combination of germplasms, then, indeed, we shall have got at the laws of inheritance.

As for the other factor, that of variation, I anticipate interesting developments in our knowledge of its laws and of its causes. The methods by which this knowledge is to be acquired are doubtless comparative observation, experimentation and a quantitative study of results. Within the last decade a profouud student of variation (Bateson) has declined to discuss its causes, holding that we had no certain knowledge of them. Even the categories of variation are still unenumerated. The science of variation is therefore one of those that we may hope to see established in this century. I feel convinced that statistical studies are first of all necessary to lay the foundations of the science.

As an illustration o. an application of statistics to evolution studies I will give some account of my work during the past two years on the scallop of our east coast, *Pecten irradians*.

Pecten irradians is a bivalve mollusc of flattened lenticular form that inhabits our coast from Cape Cod southward. The Cape Cod limit is a rather sharp one, but southward our scallop passes gradually into the closely related forms of the South American coast. This fact would seem to indicate its southerly origin. To get light on the evolution of the group, I have studied and measured more than 3000 shells, chiefly from four localities:—(1) Cold Spring Harbour, Long Island; (2) Morehead, North Carolina; (3) Tampa, Florida; and (4) the late Miocene or early Pliocene fossils of the Nansemond River. The fossil shells, to which I shall frequently refer, were found embedded in the sand of Jack's Bank, one mile below Suffolk, Virginia. The bank rises to a height of twenty-five to thirty feet. Shells were obtained from three layers, respectively one foot, six feet and fifteen feet above the base of the bluff. Of course, the upper shells lived later than the lower ones and may fairly enough be assumed to be their direct descendants. The time interval between the upper and lower levels cannot be stated. As I have measured sufficient shells from the bottom and top layers only I shall consider them chiefly. I wished to get recent Pectens from this locality, but the nearest place where they occur in quantity is Morehead, North Carolina. These Pectens may therefore stand as the nearest recent descendants of the Pectens of the Nansemond River.

The Pecten shells have a characteristic appearance in each of the localities studied. After you have handled them for some time you can state in 95 per cent. of the cases the locality from which any random shell has come. First of all the shells differ in colour, especially of the lower valve. In the specimens from Cold Spring Harbour this is a dirty yellow, from Morehead, yellow to salmon, from Tampa, white through clear yellow to bright salmon. Second, the anterio-posterior diameter of the shell becomes relatively greater than the vertical diameter as you go north. Thus the anterio-posterior diameter exceeds, on the average, the dorso-ventral diameter: at Tampa, by about 1·5 mm.; at Morehead, 2·5 mm.; and at Cold Spring Harbour, 6 mm. The fossil Pectens have an excess of about 4 mm.

Comparing the fossils with the Pectens of Morehead we find, as shown above, that the fossils are more elongated. Comparing the depth of the right valves having a height of 59 mm. we get:—

From the lowest level, Jack's Bank ...	8·8 mm.
,, ,, highest ,, ,, ,, ...	9·1 mm.
,, Morehead	19·7 mm.

Hence the recent shells are much more nearly spherical than the fossils—there is a phylogenetic tendency toward increased globosity.

The average number of rays in the different localities is as follows:—

Lower level, Jack's Bank	22·6
Middle ,, ,, ,, ...	22·1
Upper ,, ,, ,, ...	21·7
Morehead and Cold Spring Harbour	17·3
Tampa	20·5

Here it appears that there is a phylogenetic tendency toward a decrease in the number of rays of *Pecten irradians*. To summarise: the scallop is becoming, on the average, more globose, and the number of its rays is decreasing, and its valves are probably becoming more exactly circular in outline. The foregoing examples illustrate the way in which quantitative studies of the individuals of a species can show the change in its average condition, both at successive times and in different places.

But the quantitative method yields more than this. It is well known that if the condition of an organ is expressed quantitatively in a large number of individuals of a species the measurements or counts made will vary, *i.e.* they will fall into a number of classes. The proportion of individuals falling into a class gives what is known as the "frequency" of the class. Now it appears that in many cases the middle class has the greatest frequency (and is consequently called the mode), and as we depart from it the frequency gradually diminishes, and diminishes equally at equal distances above and below the mode. One can plot the distribution of frequencies by laying off the successive classes at equal intervals along a base line and drawing perpendiculars at these points proportional in length to the frequency. If the tops of these perpendiculars be connected by a line there is produced a "frequency polygon." The shape of the frequency polygon gives much biological information. When the polygon is symmetrical about the modal ordinate we may conclude that no evolution is going on; that the species is at rest. But very often the polygon is more or less unsymmetrical or "skew." A skew polygon is characterised by this, that the curve runs from the mode further on one side than on the other. This result may clearly be brought about by the addition of individuals to one side or their subtraction from the other side or the normal frequency curve. The direction of skewness is toward the excess side. The skew frequency polygon indicates that the species is undergoing an evolutionary change. Moreover, the direction and degree of skewness may tell us something of the direction and rate of that change. There is one difficulty in interpretation, however, for a polygon that is skew may be so either from innate or from external causes. In the case of skewness by addition we may think that there is an innate tendency to produce variants of a particular sort, representing, let us say, the *atavistic* individuals. In this case skewness points to the past. The species is evolving *from* the direction of skewness. In the case of skewness by subtraction, there are external causes annihilating some of the individuals lying at one side of the mode. Evolution is clearly occurring away from that side and *in* the direction of skewness.

Now so far as we know at the present time there is no way or distinguishing skew polygons due to atavism from such as are due to selective annihilation. But in many cases at least the skewness, especially when slight, can be shown to be due to atavism; and this is apparently the commoner cause. This conclusion is based first upon a study of races produced experimentally and whose ancestry is known, and secondly upon certain cases of compound curves. Take the case of the ray flowers of the common white daisy. A collection of such daisies gathered in the field and studied by De Vries gave a mode of 13 ray flowers with a positive skewness of 1·2. The 12- or 13-rayed wild plants were selected to breed from, and their descendants, while maintaining a mode at 13, had the increased positive skewness of 1·9. The descendants of the 12-rayed parents had a stronger leaning towards the high ancestral number of ray flowers than the original plants had. The 21-rayed plants were also used to breed from. Their descendants were above the ancestral condition as the descendants of the 12-rayed plants were below. The skewness $-0·13$ is comparatively slight. In this case we have experimental evidence that curves may be skew *toward* the original ancestral condition.

Of the compound polygons it is especially the bimodal polygon that frequently gives hint of two races arising out of one ancestral, intermediate condition. Consequently we should expect the two constituent polygons to be skew in opposite directions; and so we usually find them to be. For example, Bateson has measured the horns of the heads of 343 rhinoceros beetles and has got a bimodal polygon. The polygon with the lower mode has a skewness of +0·48; that with the higher mode a skewness of −0·03. One might infer that the right-hand form, the long-horned beetles, had diverged less than the short-horned from the ancestral condition. Again, as is well-known, the chinch bug occurs in two forms—the long-winged and the short-winged. Now, in a forthcoming paper my pupil, Mr. Garber, will show that the frequency polygon of the short-winged form has a skewness of +0·44, while that of the long-winged form has a skewness of −0·43. On our fundamental hypothesis the ancestral condition must have been midway between the modes.

Still a third class of cases that gives evidence as to the significance of skewness is that where two place modes have moved in the same direction but in different degrees. Thus the index (breadth ÷ length) of the shell of *Littorina littorea*, the shore snail, as measured by Bumpus has, at Newport, a mode of 90; at Casco Bay, of 93. The skewness is positive in both places and greater (+·24) at the more southern point than at Casco Bay (+·13). This indicates that the ancestral races had a higher index even than those of Casco Bay, probably not far from 96, and also that the *Littorina littorea* of our coast came from the northward, since the northern shells are the rounder. We have historical evidence that they did come from the northward. Likewise the Littorinas from South Kincardineshire, Scotland, have a modal index of 88 and a skewness of +0·065, while those of the Humber, with a mode of 91 have a skewness of +0·048. These figures suggest that if the mode were 97 the skewness would be 0, and this would give practically the same value to the ancestral index as arrived at for the Littorinas of our coast. It will be seen from these illustrations that the form of the frequency polygon may be of use in determining phylogeny.

While skewness is thus often reminiscent, we must not forget the possibility that it may be, in certain cases, prophetic. This has come out rather strongly in a piece of work I have been engaged on during the past year. I have been counting the number of rays in recent *Pecten irradians* from various localities, and have obtained in some cases evident skewness in the frequency polygons. To see what phylogenetic meaning, if any, this skewness has I sought to get a series of late fossils. After careful consideration I was led to go to the Nansemond River for the late Tertiary fossils found there and already referred to; these served my purpose admirably. We may now compare the average number of rays from the two extreme layers at Jack's Bank and at Morehead with the indices of skewness of the frequency polygons from the same localities.

Place.	Av. No. of rays.	Index of skewness	σ
Morehead, N.C.	17·3 ...	−0·09 ...	0·81
Upper layer, Jack's Bank ...	21·7 ...	−0·16 ...	1·10
Lower ,, ,, ,, ...	22·6 ...	−0·22 ...	1·24

This series is instructive in that it tells us that the gradual reduction in number of rays has been accompanied at each preceding stage by a negative skewness. This skewness was thus prophetic of what was to be. The skew condition of the frequency polygon we may attribute to a selection taking place at every stage, and the interesting result appears that the selection diminishes in intensity from the earliest stage onward. It is as though perfect adjustment were being acquired. If adjustment were being perfected we might expect a decrease in the variability in the rays at successive periods. And we do find such a decrease. This is indicated in the last column, where σ stands for the index of variability. From this column it appears that the variation in the number of rays has diminished from 1·24 rays in the Miocene to 0·81 ray in recent times. This fact again points to an approach to perfection and stability on the part of the rays. Exactly why or wherein the reduced number of rays is advantageous I shall not pretend to say. It is quite possible that it is not more advantageous, but that there is in the phylogeny of *Pecten irradians* an inherent tendency towards a reduction in the number of multiple parts. As a matter of fact there are other Pectens in which the number of rays is less even than in irradians.

The reduction in the variability of the rays with successive geological periods has another interest in view of the theory of Williams and of Rosa, according to which evolution and differentiation have of necessity been accompanied by a reduction in variability. Evolution consists, indeed, of a splitting off of the extremes of the range of variation, so that in place of species with a wide range of variability we have two or three species each with a slight range of variability. In the particular case in hand, however, it is not certain that the lower Jack's Bank form-unit (named *Pecten eboreus* by someone) has given rise to any other form than something of which *Pecten* "*irradians*" of Morehead is a near representative. The evidence indicates that the reduced variability is solely the effect of the skewing factors.

The upshot of this whole investigation into the biological significance of skew variation is, then, this: Skewness is sometimes reminiscent and sometimes prophetic. In our present state of knowledge it is not possible by inspecting a single skew curve to say which of the two interpretations is correct in the given case. But by a comparison of the frequency curves of allied form-units the state of affairs can usually, as in the examples given, be inferred. A method of interpreting the single skew curve is a discovery for the future.

I realise that I have been bold, not to say rash, in this attempt to forecast the zoology of the twentieth century. I suppose, after all, I have merely expressed my personal ideals. Let those comfort themselves, therefore, who like my picture not and let them draw one more to their taste. These matters of detail are after all less important, but the general trend of the science I believe to be determined by the great general laws that will hold, whatever the detailed lines of development. First, students of the science will cling closer to inductive methods without abandoning deduction. Speculative web-spinning will be less common, will be less attractive, and will be more avoided by naturalists of repute. Great generalisations will be made, of course, but made with caution and founded at every step on facts. Second, the science will deal more with processes and less with static phenomena; more with causes and less with the accumulation of data. The time is coming when the naturalist who merely describes what he sees in his sections will have neither more nor less claim for consideration than he who describes a new variety of animal. It is relations, not facts, that count. Third, the science will become experimental, at least in so far as it deals with processes. Nothing will be taken for granted that can be experimentally tested. Better experimental laboratories will be founded and larger experimental stations, such as Bacon foresaw in the new world, will be established. Fourth, the science will become more quantitative. This is the inexorable law of scientific progress, at least where processes are concerned. I repeat that there is no reason to expect or desire the abandoning of the lines of work already recognised and followed for a half century or more. Rather, holding fast to and extending the old lines of investigation, zoology will be enriched by new fields of study lying between and uniting the old. As chemistry and physics are uniting and occupying the intervening field, as geology and botany are coming close together in plant ecology, so will zoology and mathematics, zoology and geology, zoology and botany find untouched fields between them and common to them. Working in these new fields and by the aid of new methods the naturalist of the future will penetrate further into the nature of processes and unravel their causes.

The zoology of the twentieth century will be what the zoologist of the twentieth century makes it. One hundred years ago the prerequisites of the naturalists were few, and the opportunities of getting them were small. He must have studied with some master or have worked as an assistant under a naturalist in some museum. The places were few, the masters often difficult of approach. Now, while on the one hand the training required is vastly more exacting, on the other hand the opportunities are generous. Just because of the fact that zoology is spreading to and overlapping the adjacent sciences, the zoologist must have his training broadened and lengthened. A zoologist may well be expected to know the modern languages (let us hope this requirement may not be further extended), mathematics through analytics, laboratory methods in organic as well as inorganic chemistry, the use of the ordinary physical instruments, advanced geology and physiography, botany, especially in its ecological, physiological and cytological aspects, and animal palæontology. The list of prerequisites is appallingly long; zoologists of the future will be forced to an earlier and narrower specialisation, while at the same time they must lay a broader foundation for it.

But if the prerequisites of the zoologists are to be numerous, their acquisition will be easy. Even now scores of universities put the services of the best naturalists at the disposal of students, and offer free tuition and living to come and study with them. Libraries, great museums, great teachers are made available to him who would work and had the requisite capacity.

All these advantages will, however, count for nothing if zoological research do not attract the best men and if the best men be not accorded time and means for research. Our best students slip from our grasp to go into other professions or into commerce, because we can offer them no outlook but teaching, administration, and a salary regulated by the law of supply and demand. We must urge without ceasing upon college trustees and corporations the necessity of freedom for research and liberal salaries if America is to contribute her share to the advance of zoology in the twentieth century.

THE CARNEGIE TECHNICAL SCHOOL AT PITTSBURG.

TWO of the addresses delivered by presidents of sections of the American Association for the Advancement of Science at the recent Denver meeting were concerned with scientific and technical education. Mr. J. A. Brashear, Chancellor of the Western University of Pennsylvania, described the plans, drawn up at Mr. A. Carnegie's request, for a great technical college at Pittsburg, and Prof. C. M. Woodward, Dean of the School of Engineering and Architecture, Washington University, St. Louis, took as his text the differences between the educational ideals of to-day and of the time when education was considered merely as needful to the "embellishments of life." The movement towards a study of the materials and forces of Nature and the problem of modern life—sociological, commercial and industrial—has produced a change of front as remarkable as it is gratifying. Out of the vast extension of the horizon of human activities which the movement has promoted, and a corresponding multiplication of occupations, has come an imperative demand for better education and for technically educated men. The scheme for the Carnegie Technical School has been drawn up with the intention of suggesting how to train students to supply this want.

Reference has already been made (July 25, p. 319) to the report of the committee appointed to determine the best plan and most suitable scope of the new institution which Mr. Carnegie is prepared to build, equip and endow in the city of Pittsburg. Further details are given by Mr. Brashear in his address, and are here summarised. After a careful discussion of the plan of procedure, the committee on the plan and scope of the proposed school decided to call to their assistance, as an advisory board, Dr. Robert H. Thurston, Prof. J. B. Johnson, Dr. Thomas Gray and Dr. Victor Alderson, acting president of the Armour Institute of Chicago.

Each member of the advisory board formulated his plans without consultation with other members of the committee, yet it is a matter of interest to know that the expressed views of the advisory board as individual members were so nearly in accord on the general principles formulated for the great school of technology. The following is an outline of the scheme for the new technical school:—

First, as to site. The advisory board suggested that not less than fifty acres be secured, and as a tract of sixty-five acres is available not far distant from the Carnegie Institute, the board strongly recommended its purchase, or a similar piece of land as near by as it is possible to obtain it. A potent reason for placing the technical school near the Carnegie Institute is the fact that its library is rich in technical and other valuable works which need not be duplicated in the technical school library; indeed the association of the school with the great and increasingly valuable library, museum, art gallery and Academy of Science and Art is certainly to be desired.

As to the buildings for the technical school, but little has been suggested. Dr. Thurston in his report has given an interesting *résumé* of the space occupied by the student in the various German technical schools, remarking that the German motto "viel Platz, viel Licht, viel Luft," would be an excellent guide in determining this question. He says: "Ample space, good light and plenty of fresh air are essential, although the architect, who should be the most earnest and intelligent of them all, is often woefully deficient in appreciation of their importance when brain work is going on." Dr. Thurston further states that taking figures from the best German technical schools, which are based on the largest experience, the school of architecture at Berlin has 150 feet floor space per student, the engineering school 35 feet; but this latter department is so much overcrowded that arrangements are being made to give the student in this department at least 75 feet of floor space. In marine engineering 111 feet, and in metallurgy and the chemical departments each have 426 square feet of space. Prof. Thurston advises not less than 30 square feet per student in class rooms, in drawing rooms about 100, and in laboratories from 150 to 500 feet, according to character of the work to be done and magnitude of the space required for machinery and apparatus.

The Brunswick school has 410 feet floor space per student in all departments. At Karlsruhe 450 square feet is provided in the department of electrotechnics. The cost of the Berlin building is placed at 1000 dollars per student, of the Brunswick buildings 2000 dollars per student. From these data it may be seen that an institution which may be called upon to provide for a thousand students at once, and perhaps three or four times that number in the near future, must be planned upon a most liberal scale to meet the demands which shall be made upon it.

As to the scope of the work of the new school, Prof. Johnson's proposed scheme is as follows:—

A. Colleges. Courses of four years with a high school preparation: (1) College of Science; (2) College of Engineering; (3) College of Commerce. All these to be of university grade, with degrees conferred at graduation. B. Schools. Courses of three years with a grammar school preparation: (1) Manual Train School; (2) Domestic Science School; (3) School of Industrial Design; (4) School of Commerce. All these to be of high-school grade. Diplomas to be given at graduation. C. Artisan Day School. Courses of three years, with a preparation in reading, writing and arithmetic. To include courses of instruction in subjects of essential importance in the practice of the various trades. D. Night School for day workers. Preparation same as C. Regular courses, and also special instructions of practical value to day workers of all sorts and all employments.

Prof. Johnson, Dr. Alderson and Dr. Gray studied a number of the industries of Pittsburg, and in all their reports they emphasised the value of the secondary schools. The question of monotechnic or trade schools, *i.e.* where a young man or woman can learn at least the rudiments of a trade by which they propose to make their living, was also discussed; and it is the opinion of both committee and advisory board that in due time this part of the problem should be given earnest consideration.

Dr. Alderson recommended that the six following departments should be established, each with several branches:—(1) Engineering, (2) Secondary Education, (3) Library Economy, (4) Domestic Arts and Sciences, (5) Art, (6) Evening Instruction.

Dr. Gray recommends that the institute should offer a course of instruction covering the whole nine years of study; that it be divided into two distinct schools, a secondary and upper secondary, and a higher college or professional school. He advises that the secondary school commence first above the grade schools with a minimum age limit of fourteen years, and that the course of this instruction should include all the subjects commonly given in the best high schools with the possible exception of Latin and Greek, and in addition the subjects more commonly given in business schools or colleges, along with this course of class-room instruction, provision should be made for practical instruction, either manual or otherwise, bearing upon the particular branch of industry which the scholar intends to enter.

Dr. Gray recommends a good sound course in English for students of the secondary school, but not a study of foreign languages. He also recommends that the technical college or professional school be open only to a selected small number of students who have shown special fitness for the work, and that the entrance requirements should be considerably higher than is usual in existing technical colleges. For this department extensive laboratory practice is recommended and thorough drill in the methods of testing properties of matter and in investigational work.

The general scheme laid out for the great technical university by Dr. Thurston comprises the following colleges:—(1) Mechanical Engineering and the Mechanic Arts, with eight different departments of Mechanical Engineering; (2) Civil Engineering, with six departments; (3) Architecture, with three departments; (4) Mines and Metallurgy, with two departments;

(5) Agriculture, with six departments; (6) Applied Chemistry, with four departments; (7) Physics, with two departments; (8) Fine Arts, with three departments; (9) Business, with four departments; (10) Navigation and Marine Transportation, with two departments; (11) Mathematics, with two departments; (12) Politics and Ecomomics, with four departments; (13) Languages and Literature, with four departments; (14) Philosophical Science and Ethics; (15) Biology; (16) The Preparatory College (standard curriculum).

In his presidental address to the section of social and economical science, Prof. C. M. Woodward referred to the report of the advisory committee on the Carnegie Technical School in the following terms:—"For a variety of excellent reasons the committee reaches the conclusion that some new kind of preparation for the work of life must be introduced into the school training of both boys and girls. It then proceeds to outline a technical college, a technical high school and an artisan day and evening school, which are to meet this demand.

"The artisan day and evening school is somewhat of the order of German and English low-grade technical schools. I earnestly hope that the suggestion of this school may be adopted that the experiment may be fairly tried in America. The plan for a technical college is in complete harmony with the best engineering schools.

"The scheme for a technical high school, however, seems to me faulty. This school would be of high-school grade, taking pupils from the grammar schools and covering presumably four years. The normal ages of entrance and graduation would accordingly be fourteen and eighteen. Three things in the committee's outline of this technical high school deserve attention: (1) The elective principle is to be recognised, the student selecting the required number of courses under the direction of the director of the school. Here the pupil at a tender age (only fourteen or fifteen) is asked to surrender his birthright to the privilege of choice when he is eighteen.

"(2) The course in mathematics—which begins with elementary algebra—is to include the elements of calculus! Of course, it must include solid geometry, higher algebra, trigonometry and analytical geometry! One rarely meets with such an astounding proposition from engineers who are supposed to have studied mathematics and to know what they are talking about. They might as well propose that the pupils shall take thermodynamics in a short course of lectures. To be sure, similar ambitious schemes have been proposed elsewhere for boys just out of the grammar school, but they came from people who could have known very little mathematics, and nothing of the uses of the calculus. This criticism may seem trivial, but in more than one place the scheme attempts too much.

"(3) The technical studies suggested take the form of trade work or special employments, with well equipped shops and experimental laboratories under the direction of expert artisans.

"What Mr. Carnegie will do with this last suggestion remains to be seen, but any attempt to embody it in a real technical high school of secondary grade will be full of interest to the educational world. If any man was well prepared to give the scheme a fair trial, that man is Andrew Carnegie; but it will cost a vast amount of money and its experience will teach us how not to do many things.

"I have high respect for the members of the advisory committee, but I think a less ambitious scheme would be more successful. You cannot teach the higher mathematics in a high school, and I have no great faith in the value of attempts to teach employments, commercial or industrial, within the limits of any secondary school. Such attempts are certain to mislead and ultimately hinder those they aim to help. Any trade or special employment must be dwarfed and narrowed before it can be brought down to the grasp of an untrained boy, and its very narrowness unfits it for the best educational uses.

"The school is the place where one should learn the fundamental unchanging laws and manifestations of force and materials. Special occupations, like special constructions, should be analysed in their elements, and pupils should become expert in such analyses, in so far as they involve universal elements that pupils can comprehend. But there are many things essential to a business employment, which cannot even be apprehended in school."

From the foregoing it will be seen that much difference of opinion exists as to the nature and extent of the subjects which should be included in the curriculum of a large technical school. Three different and distinct forms of school, which may be combined as parts of one complete technical university, have been proposed. If the whole scheme is accepted by Mr. Carnegie, there will be, in the first place, a first-class technical college. "This college," says the committee, "should be made attractive to the greatest scholars in the fields of physical and chemical science. To obtain and hold such men they must be given ample opportunities for research. This college must be supplied, therefore, not only with great experimental shops and laboratories for students' use, but in all departments there should be splendidly equipped laboratories of investigation and research, under the direction of the head of such department, and with a full corps of assistants for the carrying on of all lines of investigation which are now partly or wholly unprovided for in America." There will also be a Technical High School to carry on work above that of the public grammar school, and day and evening classes for the benefit of those who are unable to take advantage of the more complete courses in this school. Mr. Carnegie has now to decide whether he will found a school for artisans, a technical high school or a technical college, or, if his ambition mounts so high, a true technical university including them all.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE building fund of 150,000*l.*, which it is proposed to raise for the Glasgow and West of Scotland Technical College, has reached about 100,000*l.*, and Mr. Carnegie has promised to subscribe one-half the deficiency upon the condition that the other half is promptly obtained.

THE position of science and technical instruction in schools inspected by officers of the Secondary Branch of the Board of Education can be seen in vol. ii. of the Report just issued by the Board, containing extracts from the inspectors' reports for the year 1900. Improvement is manifest in the larger technical schools in the teaching of advanced science. General improvement is also reported in the mode of teaching experimental science. "Moreover," remarks Mr. A. E. Tutton, F.R.S., "the influence of the advocates of the heuristic method of teaching has proved to be so far effective that the general attention of teachers has been directed to the educative value of calling forth the highest thinking and experimenting powers of their pupils." Dr. H. H. Hoffert also reports that "there is amongst the teachers a widely spread spirit of enthusiastic eagerness to ascertain the best methods of instruction and to apply them in their own schools." The movement for reform is being felt in the teaching of mathematics, and Mr. J. Brill contributes a short special report upon the subject to the volume just issued. The work being done in the Schools of Science is favourably reported upon by all the inspectors. In these schools five or six hours a week are given to experimental science, two or three to drawing and geometry, about five to mathematics, and eight or ten to literary subjects. Beyond this minimum requirement the extra time at the disposal of the school is given to languages, to science, to commercial subjects, or to manual occupations according to the particular type of the school. In fact, these schools possess a curriculum which is adapted to modern requirements, and in most of them excellent work is being done, not only in science and art, but also in literary subjects.

A FULL report of the opening of the Harper-Adams Agricultural College at Edgmond, Newport, by Mr. Hanbury, the President of the Board of Agriculture, appears in the *Newport and Market Drayton Advertiser* of September 28. The College owes its establishment to the late Mr. Thomas Harper-Adams, who left a large sum of money and an estate in order to found it. It is provided with lecture rooms and laboratories in which work can be carried on in physics, chemistry, biology, and other sciences connected with agriculture. The farm attached to the College is about 180 acres in extent and is intended for experimental purposes; and all the work will be arranged with the object of instructing students in the practical management of a farm on modern business lines. The Salop County Council make a grant of 1000*l.* a year towards the College funds, and together with the Stafford County Council offer a certain number of scholarships tenable at the College. The Principal is Mr. P. Hedworth Foulkes. In opening the College, Mr. Hanbury referred to the small sum available for agricultural education. At present the Board of Agriculture had to spend, in grants, the small sum of 8000*l.* for the whole of the United Kingdom. In France, for the same purpose, 153,000*l.*

is granted by the State. In Denmark, 108,000*l.* is granted; in Canada, 156,000*l.*; and in the United States, 26,000*l.* Moreover, a comparison of the assistance given to agriculture with that given to the towns shows that out of the Science and Art grants given by the Board of Education, no less than 505*l.* out of 506*l.* goes to the towns, and only 1*l.* to the rural population. Referring to the value of agricultural colleges and scientific work to the practical farmer, Mr. Hanbury remarked that it was sometimes asked, What is the good of science? He took science to mean this, however practical a man might be, it was impossible for him, in his own experience, to have learned everything. What science meant was, that other people had been experimenting, and had found that those experiments had been a success, and that it made money to work in that way. He therefore asked them not to be afraid of the word "science"; and, above all, not to think, because they were practical men, that they knew everything, for there was no trade in the world in which there was any man who had occupied the whole region of science, or the whole region of knowledge. He thought they made a mistake in making experiments over and over again. He was a little afraid the County Councils, in too many instances, were going over the same ground over and over again. What was to be of some use to farmers was that those experiments had been made, and the results proved to be true. He should like to see more demonstrations made all over the country—not mere pocket handkerchief demonstrations over a small field, but, if they were to be any good, over several fields of a farm.

SCIENTIFIC SERIAL.

American Journal of Mathematics, vol. xxiii. No. 4.—Memoir on the algebra of symbolic logic is the second part of a paper by Mr. A. N. Whitehead, which treats of the theory of substitutions under the heads, types of transformation, relations between the coefficients of a substitution, the reverse substitution, the group of substitutions, substitutions satisfying special conditions, congruence of functions, the identical group of a function, and common subgroups of identical groups.—Secular perturbations of the planets, by G. W. Hill, follows up Halphen's presentation of Gauss' procedure (*Werke*, vol. iii. pp. 331–355). The author thinks that, though a remarkable degree of elegance is attained by Halphen's changes, additional statements are needed to show the connection with the astronomical problem which originally suggested the investigation; for Halphen, like Gauss, treats only the attraction of a certain form of ring. This ignores the second integration which the problem demands. The present memoir attempts to supply the lacuna.—Representation of linear groups as transitive substitution groups, by L. E. Dickson, is a piece of work on the well-known lines of this mathematician.—A class of number-systems in six units, by G. P. Starkweather, is a further contribution to the same subject which was treated of by the author in vol. xxi. No. 4.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, September 16.—M. Bouquet de la Grye in the chair.—Demonstration and use of the formulæ relating to the refractometer, by M. A. Cornu.—On the elastic arch, by M. G. Poisson.—On the simultaneous employment of multiplex and ordinary telegraphy in the same circuit, by M. E. Mercadier.—On the molecular weight of chloral hydrate at the temperature of its boiling point, by M. de Forcrand. By a discussion of thermochemical data the author arrives at the conclusion that at the boiling point chloral hydrate is not totally dissociated, from 4 to 5 per cent. remaining undissociated.—On dunite from Koswinsky-Kamen, in the Ural, by MM. K. Duparc and F. Pearce. The results of a microscopical and chemical study of the dunites from this district.—A new cave with drawings on its walls of the Palæolithic period, by MM. L. Capitan and H. Breuil. An account of the discovery of a cave situated at Combarelles, in Tayac (Dordogne), about two kilometres from the Mouthe cave. The cave is about 225 metres long, and about 119 metres from the entrance drawings can be seen on the walls, which continue to the end of the cave. They are engraved upon a cretaceous rock, but the greater number are covered with a stalagmitic deposit, which is sometimes so thick that the lines cannot be seen through it. No less than 109 figures can be clearly made out, including drawings of the horse, cow, bison, reindeer, mammoth, and wild goat. It would appear that these drawings, the antiquity of which cannot be doubted, could only have been executed by artists reproducing animals that they saw. Hence they are clearly Palæolithic, and go back to the epoch when the mammoth and the reindeer lived in France.—Luminous rays diverging at 180° from the sun, by M. Jean Mascart.

September 23.—Binary systems and couples of kinematic elements, by M. G. Kœnigs.—Lecithin in tuberculosis, by MM. H. Claude and A. Zaky. Experiments on animals and on man showed that lecithin, owing to its specific action on the elimination of phosphates by the urine, has a remarkable action on the nutritive exchanges, and it must be considered as a valuable adjunct to the various modes of treatment of tuberculosis.—On the ravages of the pyralis in the Beaujolais, and on the destruction of the night moths by means of luminous traps fed with acetylene, by MM. G. Gastine and V. Vermorel. The traps consisted of basins containing water covered with a layer of oil, above the centre of which was placed a small acetylene lamp to attract the insects. By this method between August 13 and 31 no less than 170,000 pyrales were destroyed.—The distribution of acidity in the stem, leaf, and flower, by M. A. Astruc. The acidity of the stem diminishes with the distance from the top. In the case of the leaves the acidity is greatest in the youngest leaves, and in general it is always the youngest parts of the plant which present the maximum acidity.—A new cave with figures on its walls of the Palæolithic period, by MM. L. Capitan and H. Breuil. A description of the drawings on walls of a cave at Font-de-Gaume, situated in the valley of the Beune, about two kilometres from the cave of Combarelles. The drawings consist largely of animals, of species resembling those represented in the cave of Combarelles. These drawings are noteworthy for the fact that different colours have been used, black, red, and brown. They are probably not so ancient as the drawings on the walls of the cave at Combarelles.

NEW SOUTH WALES.

Royal Society, August 7.—Prof. T. W. Edgeworth David, F.R.S., vice-president, in the chair.—Notes on some analyses of air from coal mines, by A. A. Atkinson and F. B. Guthrie. The authors gave the analyses of several samples of air from the return air-ways at Wallsend and Burwood collieries, and of gases produced by fires in the Gunnedah and Greta collieries, the latter was an old gob. fire. The analyses were compared with published analyses of air in the return-ways of English collieries made by Dr. Haldane, and the question of the effects of diminution of oxygen, presence of carbonic acid, black-damp and other injurious gases found in the air of coal-mines, discussed in relation to their action on men and lights.—Symmetrically distorted crystals of Cassiterite from Western Australia, by W. G. Woolnough.

RATIONAL GEOMETRY.

Plane and Solid Geometry. By Arthur Schultze, Ph.D., and F. L. Sevenoak, A.M., M.D. Pp. ix+370. (New York: The Macmillan Company, 1901. London: Macmillan and Co., Ltd.) Price 6*s.*

THIS is an excellent work for all young students who wish to begin the study of geometry. In its order of treatment it completely ignores Euclid, and thus saves the young pupil from a long and wearisome waste of time, giving him clearly and rapidly a knowledge of the subject and an insight into its nature and purpose. We wish that the English schoolboy could congratulate himself on its appearance; but this is forbidden by our conservatism and the attachment of our public and preparatory schools to mediævalism. When an Educational Reformation takes place in England—and there are signs of its advent—such a work will be welcomed by all of us who are interested in the scientific education of the people.

The book is divided into two parts—Plane Geometry and Solid Geometry. The first part is divided into five books (225 pages), and the second into three (93 pages). The type is excellent, and the figures (especially those in the second part) beautiful.

To enter now into a few matters of detail, we would suggest to the authors that they should not have followed the English plan of beginning with a catalogue of fifty definitions before the pupil reaches the real work of the subject: this makes for tediousness. The term *straight angle* (adopted, apparently, from the A.I.G.T.) is, we think, very objectionable, because the notion of straightness should be kept quite distinct from that of an angle. The first proposition in the book, "vertical angles are equal," is Euclid's 15th; prop. 2 is Euclid's 26th; prop. 3 is Euclid's 4th; prop. 4 is Euclid's 16th. Thus a common-sense order of treatment is freely adopted. Then comes the treatment of parallel lines in which all of Euclid's results are given. The definitions of degrees, minutes, and seconds are given in the preliminary definitions (p. 5), but the protractor is not mentioned, so that the actual way of reading the value of a given angle is not exhibited. This omission of the protractor seems to us to be a mistake. Some propositions are merely enunciated, and, instead of a formal proof, a "hint" to the pupil in a few words is given. This is good, because it exercises, without severity, the power of the young thinker. The famous Asses' Bridge is given as prop. 14, with the mere hint that it would be obvious if the bisector of the angle at the vertex were drawn—as, of course, it would be. Herein observe the contrast to Euclid, who would not allow us to use this bisector unless he had previously shown how to construct it—a perfectly useless restriction which runs through the whole of Euclid. Of course it is subsequently shown (p. 35) how to bisect an angle and a line. The authors are generally precise in their use of language, without adopting the grotesque show of accuracy in our school Euclids. Nevertheless, they occasionally make an absurd use of the word *respectively*, which is so prominent in these works. Thus (p. 30), "two triangles are equal if the three sides of the one are respectively equal to the three sides of the other"; clearly no *order* of equality is necessary. See also end of p. 74.

In p. 33 and elsewhere the authors boldly define a circle as an area, and distinguish it from its bounding curve, which they call "a circumference." If we punch a wad out of a sheet of cardboard, which area has the right to be called the circle—the wad or the whole of the outside area of the sheet?

In this respect, however, the authors are consistent, while Euclid is not. Euclid's formal definition makes the circle an area, while in his Book III. he says that two circles cannot have more than two points in common.

The English barbarism involved in the proposition "if two sides of a triangle are equal, the opposite angles shall be equal," is consistently avoided, the simple word "is" or "are" being always used instead of the compulsory and ridiculous "shall be" of our school Euclids.

The second book of Part i. treats of the circle, and travels over the ground of Euclid's III. and a little more, arithmetical examples being occasionally given—a great desideratum in our English system. Here measurement and ratio are introduced, as well as the notion of limits—a great improvement. Euclid's first book problem, "to construct a triangle when its three sides are given," appears here as prop. 19—a postponement of more than doubtful value.

The third book is on proportion and similar polygons, and the propositions are illustrated and explained by simple algebra and arithmetic; thus the beginner can learn the essence of the subject in a few minutes without wasting a lifetime on Euclid's Book V. In this book the authors give the propositions relating to the equality of areas, of triangles, and parallelograms, while the proposition of Pythagoras now appears for the first time (p. 147), founded on the similarity of the two triangles into which a "right triangle" is divided by the perpendicular from the vertex on the hypothenuse; the old proof and time-honoured figure are, however, given in the next book (p. 178). Near the end of the third book we have Euclid's well-known proposition whose trigonometrical form is $c^2 = a^2 + b^2 - 2ab \cos C$, the proof being, of course, geometrical, but presented in algebraic form.

The fourth book treats of the areas of polygons, and the proofs are presented in algebraic form. The exercises all through are numerous and very appropriately placed.

In the part dealing with solid geometry and the fundamental properties of spherical triangles, the figures are, as we have said, exceedingly good and realistic.

In p. 264 we have the proposition "the sum of any two face angles of a triedral angle is greater than the third face angle"; but the proof will have to be slightly modified, as, in its present form, it is confusing for the beginner. Thus, to the words "in the face AVC draw VD equal to VB, making $\angle$ DVA = $\angle$ BVA," it may fairly be objected that this is impossible if the points A and C are already given. The line VD should first be drawn, and then the lines ADC and BC. Again, in

p. 205, the proposition "the circumference of a circle is less than the perimeter of any enveloping line" has no special reference to a circle—it is true of any oval figure whatever, and no special property of the circle is employed in the proof. We think that it should be struck out as misleading. Finally, we must point out that the Socratic method of teaching the pupil by a system of questioning—the most efficient of all teaching methods —is adopted throughout the book. The limited space at our disposal has not by any means allowed of such an exhaustive exhibition of its merits as this work deserves. GEORGE M. MINCHIN.

NATIVE LIFE IN SOUTHERN INDIA.

Occasional Essays on Native South Indian Life. By Stanley P. Rice, Indian Civil Service. Pp. vi + 223. (London: Longmans, Green and Co., 1901.) Price 10*s.* 6*d.* net.

THESE sketches of south Indian life are concerned, not with any of the districts, like Madura or Tanjore, in the extreme south of the peninsula, but with Ganjam, which while politically connected with the Madras Presidency, is by the race, language, and customs of its people more closely linked with the Bengal Province of Orissa. This political separation from his northern kinsfolk has worked evil to the Uriya of Ganjam. The ordinary Madrasi looks on him as an inferior creature, "not merely low in the rank of civilisation, but incapable of better things"; and he is carefully excluded from the official employment which is monopolised by his Telegu neighbours in the south. Hence, as might have been expected, he has no ambition to develop his own language or literature, and he remains a boor, slovenly in his mode of life, and with little love for the foreign native officials who manage his affairs. But he is not quite destitute of good qualities. He is a hard-working farmer; he is not given to drink, like the Telegu; and Mr. Rice vouches for the fact that, when addressed in his own tongue by one who understands and appreciates him, he is courteous and hospitable. But still there is a vein of savagery beneath his boorish exterior, as is shown by the graphic account given by Mr. Rice of the so-called Rebellion of Parlakimedi, which plunged the land in ruin and anarchy during the early years of last century. As usual in such cases, it arose from the apathy and ignorance of the early officials; and it was not till many years had passed in maladministration that a strong man was found at last in Mr. George Russell, one of those little-known heroes of our Indian services, who gave the land peace which has never since been disturbed.

Mr. Rice, though a careful and sympathetic observer of native life, seems to have little knowledge of Indian anthropology and folklore. This is perhaps not an unmixed disadvantage. He does not come, like some of our Indian officials, ready to apply book learning to the study of savage life; nor is he primed with that modicum of acquaintance with comparative anthropology which leads him to see a totem in every bush, or a tree-god in all rural ceremonies. But had he possessed a wider acquaintance with some of the problems which anthropology attempts to solve, his studies could have hardly failed to gain in precision and interest.

We have in Ganjam an excellent example of three overlapping races. The Uriya of the plain country is a Dravidian with a certain amount of Aryan intermixture. His language is not "a blend of Sanskrit and Hindustani," but a form of Bengali affected by the Telegu or other South Indian tongues. A wider study of linguistics would make it clear to Mr. Rice that the word Ponda for a priest, which puzzles him, is merely the Sanskrit *panda*, "a learned man."

Next on the lower hills come the Khonds or Khânds, who seem here to have preserved no tradition of the Meriya sacrifice through which they are best known to ethnologists. They are a race of half savages already half ruined by the trickery of the Uriya Shylock, and deprived of their old mode of livelihood in the jungles by the repressive rules of the Forest Department.

Still further back in the more remote hills are the Savaras or Sauras, who enjoy a free savage life, periodically burning down the jungle to sow their scanty crops, but living mainly on the fruits and roots which the forest supplies. But they possess some traditions of a more settled life, because it is their law that the dead man must be cremated with the wood of the mango, and this must be done "in the portion of ground—one cannot call it a field—which he last occupied." Of course this may be a sign of Hindu influence, but Mr. Rice does not say so, and Mr. Risley's account of the race in Bengal does not support the suggestion.

Of the marriage rites of these jungle people Mr. Rice gives some interesting details, but he misses the point of some of their practices because he has not grasped the fact that they indicate a reaction against the early custom of "Beena" marriage, in which the bridegroom is adopted into the clan of his wife. This still prevails among the Savaras, where if the bride's father agrees to the alliance, "he and the bridegroom elect to go into partnership and cultivate for two or three years."

The religion of these races is, as usual, of the animistic type, but it has been largely influenced by the Orissa cult of Jaggannâth. Witchcraft, of course, and the custom of rendering the witch harmless by knocking out the teeth, prevail widely. Special respect, which may be totemistic, but is more probably the survival of some animal cult, is paid to the bear, "as they have a curious fancy that the souls of their ancestors inhabit the bodies of bears after leaving their human prison." Mr. Rice has never been able to discover why, when building a house, they plough up the site and sow some grain after consulting a priest or seer. This is a common form of mimetic magic, performed with a view to ensure the prosperity of the household.

We trust that if Mr. Rice has the good fortune to be again posted to such an interesting district as Ganjam he will continue his studies among those wild races about whom he displays such a sympathetic interest. But he would come better prepared for such inquiries if he mastered Mr. Risley's account of the tribes of Bengal and other equally accessible works on Indian ethnology and folklore.

THEORETICAL EXPLANATIONS OF GEOLOGICAL FACTS.

Essai d'une Explication par les Causes actuelles de la Partie théorique de la Géologie. Par H. Hermite. Pp. 115. (Neuchâtel: Attinger, 1901.)

M. HERMITE believes that the facts of geology admit of much simpler theoretical explanations than they have hitherto received. Whether his substitutes will be generally adopted is, we think, open to question; but as it would be a lengthy business to criticise them in detail we must restrict ourselves to a brief outline of their leading features. Mountain-making is not, as is generally thought, the result of a cooling of the liquid earth's interior, for that is not in accord with the theory of heat. It is caused thus:—The crust is very flexible. Materials deposited upon it produce a downward movement in that part with a corresponding upward one in another, so the ocean basins are constantly sinking and the continents rising. This upward movement is concentrated on the periphery of the basins, where the strata are bent, strained, and finally fractured. Motion is converted into heat and the temperature of this zone is elevated. It then communicates heat to the adjacent ocean, and thus increases evaporation. That results in a heavier rainfall. The precipitated water works down into the rising land, thus cooling it, and producing of course the greatest effect nearest to the surface. So the rise of temperature observed in sinking wells, &c., is due to a local cooling rather than to the cause usually assigned. That the consequence of mountain-making is abundant rain is proved by the prevalence of sandy deposits in the earliest geological ages. Another consequence is that periods of extensive and rapid deposit of detritus are succeeded by others of slow and regular sedimentation. M. Hermite passes on to explain the occurrence of the warm era with which the earth's history began, and the glacial epoch of its later days. Crust cohesion, he says, was great in early times, so more material was needed to make it sink; and thus the rise of temperature of the basins was greater. Evaporation was thereby increased and the whole surface covered with a veil of mist, resulting in a mild, uniform climate. But the heavy rains penetrating into the crust ultimately chilled it, and the streams which they produced cooled the ocean, till things returned to their former condition. As the cohesion afterwards became gradually less, this universal, warm, damp atmosphere did not recur, and the loss of heat by radiation gave rise to the seasons. But earth movements were augmented about the time of the passage of the Tertiary into the Quaternary, and led to precipitation which supplied the snow for the great glaciers. Thus this epoch was brought to an end rather by the diminished warmth of the ocean waters than by a rise of the general air temperature. At the present day the great glaciers of the Polar regions are largely fed by the water emitted from volcanoes. The Carboniferous period seems to have been a turning point in the history of the globe; for the crust up to that time was less fissured, and so was not chilled by the penetrating water; hence the high temperature of the seas kept the carbonic acid in the atmosphere. But after that became fixed in the form of coal the present conditions became possible. M. Hermite, we think, is not likely to get his theory adopted by geologists until he shows in more detail that it will harmonise with the facts; for he usually contents himself with vague statements, which read like his impressions of books. Also, when he plays havoc with the names of fossils (*e.g.*, *Rhinocéros*, *Thycorinus*, for *R. Tichorhinus*), and attributes the cirques and gorges of mountain regions, with the cañons of more level districts, to the action of subterranean water, we feel that he is making a possible exception a general rule, and we cannot help doubting whether he has any practical knowledge of the science. In fact, much of his geology seems on a par with his statement (p. 29) that the volume of a series of spherical shells increases as the cube of their radii.

OUR BOOK SHELF.

La Géologie. Par H. Guède. (Bibliothèque des Sciences Contemporaines.) Pp. 724. 151 figures intercalées dans le texte. (Paris: Schleicher Frères, 1901.)

IN his very modest preface, the author of this volume disclaims any idea of adding to the accumulated mass of geological facts or of advancing new theories to account for them. His object is to present, in a lucid manner, a summary of acknowledged facts and generally received theories, following the encyclopædic treatise of M. de Lapparent, and to do so in such a way as to make the subject of interest to the general reader, while avoiding the claptrap style of certain so-called popular works.

In a task of this kind there is not much opportunity for originality of treatment, and the author wisely follows the general plan of geological treatises in discussing first the causes at present in operation in the earth's crust, secondly the changes in the earth's surface features, thirdly the internal forces at work within the earth's crust, and fourthly the evolution of the earth. In his classification of the geological periods, the author follows most French writers in treating the Quaternary era as the equivalent of the Tertiary, Secondary and Primary eras, a plan which is not without inconvenience to the student. The illustrations of the book appear to be all original, and are of a very simple character—indeed, nothing more than transcripts of such rough sketches as a teacher would draw upon the blackboard. While this plan has the advantage of enabling the teacher to emphasise the *essential* features in the sections and fossils he refers to—and these are often missed in more elaborate picture-illustrations—it is in some cases manifestly inadequate for teaching purposes. Thus the reader of this work would have no idea of the characters of the rocks described when seen in thin sections under the microscope. On the whole, however, the author may be congratulated on having produced, within a very moderate compass, a clear and exact exposition of geological science.

Farm Poultry. By G. C. Watson. Pp. x + 341. Illustrated. (New York: The Macmillan Company, 1901; London: Macmillan and Co., Ltd.) Price 5*s*. net.

THIS popular sketch of poultry farming is a very useful addition to the Rural Science Series. Mr. Watson has written for practical men, and gives working details on every part of his subject, but he has at the same time written in a really scientific spirit. Scientific terms are, indeed, entirely avoided; the language is clear and simple; but the principles which underlie good practice are in every case brought to the front, so that a rational acquaintance with the subject is ensured. There is, perhaps, no department of farming which suffers so much from mismanagement as the poultry yard, yet the industry is of national importance. Mr. Watson reminds his readers that the annual value of farm poultry and eggs produced in the United States, according to the census returns of 1890, exceeded the annual value of the coal, iron, and mineral oil produced during the same period. In England we have no such statistics, but the Trade and Navigation Returns show that the imports of poultry and eggs to this country amounted last year to the value of 6,416,468*l*. The book has numerous illustrations.

R. W.

The Collected Scientific Papers of John Couch Adams. Vol. ii. Pp. xxxii+646. (Cambridge University Press, 1900.)

THE astronomical papers in this volume have been ably edited by Prof. Sampson. The first eighteen papers form a connected series on the lunar theory, and are substantially the lectures on that subject which Adams used to deliver at Cambridge. As an aid to the student they probably surpass any text-book that has been written on the subject. It has been said that the difficulties of the lunar theory begin where the text-books usually leave off, but Adams introduces the reader to many of the practical difficulties of the numerical work, such as the slow convergence and small denominators.

The other astronomical papers are miscellaneous in character and must have taxed the editor to the utmost, for, to quote the preface, "the papers . . . were almost devoid of arrangement. . . . It would have been a hopeless task . . . had not almost every page been dated. This permitted reference to a diary. . . ." Among the most interesting papers are those on Jupiter's satellites, a subject which Prof. Sampson has made his own, a paper on an infinite determinant in the motion of the moon's node which shows that Adams came nearer than anyone else to anticipating Hill in his treatment of the lunar theory, and some papers on the moon's secular acceleration.

The second and larger half of the volume is devoted to Adams' papers on terrestrial magnetism edited by his brother, Prof. W. C. Adams. These consist chiefly in a determination of the Gaussian magnetic constants, a problem for which the material is even now scanty, owing to the fact that such magnetic observatories as there are, are for the most part closely grouped together in one portion of the earth's surface.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Rolling Angle of a Ship found by Photography.

WHILE crossing the Pacific Ocean between Auckland, N.Z., and Sydney, N.S.W., in the Union s.s. *Mokoia*, I wished to determine, if possible, the rolling angle of the ship by some means, other than that of the inclinometer, which the captain allowed me to inspect from time to time. As the period of rolling was long, it seemed quite possible that an ordinary kodak camera might be manipulated and a fresh film introduced, between the end of the roll to port and then to starboard. This turned out to be the case: the results are shown in the pictures A and B, which indicate the inclination of the ship to the horizon, to starboard and to port, respectively. The films when developed and finished were superposed, so that the pictures of the ship in each photograph coincided. The print made from this combination of the pictures B and A gives the composite picture C, in which the horizon in picture A is separated from that in picture B by the angle shown, which when measured with a circular protractor was found to be 19° 6′. After a few trials, no difficulty was experienced in making the exposure at the right time, viz., at the ends of a roll. Better results might have been obtained on dry plates, as films do not stand high temperatures well. The film B is very slightly distorted. The angle may also be found by means of a single picture; in this case a small stop should be used, and the exposure made for a longer period than that of one roll; the angle then appears as a rather faint fan, but the definition at the ends of the roll is not so well defined as when two pictures are made and then superposed.

A B C

Union Steamship Co.'s *Mokoia*. Rolling angle found by photography. A is a picture taken at the instant of the end of rolling to the right, S: B is a picture taken at the instant of the end of rolling to the left, P; C is a composite picture made by superposing the two films, A and B. The pictures of the ship are made to coincide, thus the angle between the two horizons in A and B is found. Lat. 34° 27′ S. Long. 157° 43′ E. To Sydney 325 miles.

Since my return to England, I find that M. Huet, of the French Navy, used a photographic method for indicating the rolling angle. But as his work on the subject is only in the hands of the French Naval Department, it cannot be consulted. His method is referred to in Sir W. White's "Manual of Naval Architecture." After obtaining the results shown in picture C, I devised an apparatus whereby the inclinometer angle may be simultaneously compared with that found by the photographic method. By this means, the positions of the inclinometer are also recorded on the films on which the horizon appears, so that the angle shown by the inclinometer may be at once compared with the angle found by the photographic method, which is entirely free from the errors inherent in pendulum inclinometers.

F. J. JERVIS-SMITH.

British Instruments at the Paris Exhibition.

IN connection with the English exhibits at the Paris Exhibition last year, it may be worth while to quote the concluding paragraph of this part of the impartial and very carefully considered report of Prof. Dufour, of Lausanne, the Swiss member of the jury.

"L'Angleterre vit, dans le domaine des instruments scientifiques, dans un isolement assez grand par rapport aux autres pays. Elle a ses habitudes et ses traditions, des instruments bien faits, mais ces constructeurs, ne paraissant guère se soucier de ce qui se fait hors de chez eux, ont peu d'influence sur l'étranger."

C. V. BOYS.

Notes on Minerals from the Lengenbach Binnenthal.

IN a recent visit to Binn I obtained some interesting minerals —viz. (1) a new mineral (2) Dufrenoysite, (3) Hyalophane.

(1) A new member of the sulpharsenites of lead, crystallising in the oblique system

$$\beta = 82^\circ 42\tfrac{2}{3}'. \quad a:b:c = 1{\cdot}36817 : 1 : {\cdot}947163.$$

Very similar to dufrenoysite in appearance, but distinguished by the rounding of the dome and pyramid planes and well-marked oblique symmetry.

I found an imperfect crystal three years ago, but it was not till last August that I obtained sufficient material to fully determine this new mineral.

(2) I also found some very finely developed crystals of dufrenoysite having fifteen new faces, also a twinned crystal, twin plane (0.1.14), thus resembling rathite, whose twin plane is (0.15.1).

(3) Hyalophane, the baryta felspar which is isomorphous with orthoclase, is now shown by some of my specimens to twin according to the Baveno and Manebach laws of twinning in orthoclase.

A full account of the above will appear in the next number of the *Mineralogical Journal*. R. H. SOLLY.

Cambridge.

Gog and Magog.

YOUR interesting paragraph in NATURE of September 26 on the local Flemish giants carried annually in procession omitted the parallel most suggestive to English readers: Gog and Magog, cousins German of Gayant and Phinar, used also to figure annually in the Lord Mayor's Show, as is noted in Chambers's Encyclopædia. According to tradition "the Guildhall giants are images of the last two survivors of a race of giants who inhabited Albion, descendants of wicked demons and the thirty-three infamous daughters of the Emperor Diocletian, who, after murdering all their husbands, sailed to Albion. These giants Brute and his Trojans finally overcame, leading the last two survivors prisoners to London, where they were kept as porters at the palace-gate. This is Caxton's account; another represents one of the giants as Gogmagog, and the other as a British giant who killed him, named Corineus. These giants have stood in London since the days of Henry V., and have witnessed all its history since. The old giants were burned in the great fire, and the new ones, which are 14 feet high, were constructed in 1708. The ancient effigies, which were made of wicker-work and pasteboard, were carried through the streets in the Lord Mayor's Shows, and copies of the present giants were in the show of 1837. Formerly other towns in England and abroad had their giants, as the Antigonus of Antwerp, 40 feet in height, and Gayant, the giant of Douay, 22 feet in height." D. P.

Edinburgh, October 3.

Fireball of September 14.

A VERY memorable meteor fell into the Atlantic on September 14, 1492, and is recorded in the diary of Columbus. It would be interesting to know whether his notes are sufficiently precise to enable one to say whether the radiant of that meteor is the same as that of more recent ones. C. E. STROMEYER.

Lancefield, West Didsbury.

A New Name for an Ungulate.

IN a paper published in the *Geological Magazine* for September 1901 I described a large ungulate from the Eocene of the Fayûm, Egypt, under the name *Bradytherium grave*. I now find that the name *Bradytherium* had been employed a few months previously by G. Grandidier for a large extinct edentate from Madagascar (*Bull. Mus. d'Hist. Nat.*, Paris, 1901, p. 54), and I therefore wish to propose the name *Barytherium* for my genus. CHAS. W. ANDREWS.

British Museum (Natural History), October 7.

ON THE MAGNETIC ROTATION OF LIGHT AND THE SECOND LAW OF THERMODYNAMICS.

IN a paper published sixteen years ago I drew attention to a peculiarity of the magnetic rotation of the plane of polarisation arising from the circumstance that the rotation is in the same absolute direction whichever way the light may be travelling. "A consequence remarkable from the theoretical point of view is the possibility of an arrangement by which the otherwise general optical law of reciprocity shall be violated. Consider, for example, a column of diamagnetic medium exposed to such a force that the rotation is 45°, and situated between two Nicols whose principal planes are inclined to one another at 45°. Under these circumstances light passing one way is completely stopped by the second Nicol, but light passing the other way is completely transmitted. A source of light at one point A would thus be visible at a second point B, when a source at B would be invisible at A; a state of things *at first sight*[1] inconsistent with the second law of thermodynamics." (*Phil. Trans.* 176, p. 343, 1885; *Scientific Papers*, vol. ii. p. 360). It is here implied that the inconsistency is apparent only, but I did not discuss it further.

In his excellent report ("Les Lois théoriques du Rayonnement, Rapports présentés au Congrès International de Physique," Paris, 1900, vol. ii. p. 29), W. Wien, considering the same experimental combination of Nicols and magnetised dielectric, arrives at a contrary conclusion. It may be well to quote his statement of the case. "La rotation magnétique du plan de polarisation constitue un cas exceptionnel digne de remarque, et l'on pourrait ici imaginer un dispositif qui mettrait en échec principe de Carnot s'il n'existait pas une compensation inconnue.

"Faisons, en effet, les suppositions suivantes; Deux corps de température égale sont entourés d'une enveloppe adiabatique. Les rayons qu'ils s'envoient réciproquement traversent deux prismes de nicol. Entre ces prismes se trouve une substance non absorbante sur laquelle agissent des forces magnétiques qui font tourner le plan de polarisation d'un angle déterminé. La radiation émanant du corps 1 pénètre dans le nicol 1. Nous supposerons que le rayon subissant la réflexion totale n'est pas absorbé, mais renvoyé dans sa propre direction par des miroirs convenablement disposés. Admettons que le plan de polarisation soit tourné de 45° par les forces magnétiques. La section principale du deuxième nicol étant orientée dans la direction parallèle au plan de polarisation du rayon émergent, toute la lumière transmise par la substance absorbante (*sic.*) traversera le nicol. Par consequent, la moitié des rayons émis par le corps 1 frappera le corps 2.

"Les rayons émis par le corps 2 se divisent en deux parties égales, dans le nicol 2. Une moitié est, comme précédemment, renvoyée par réflexion. L'autre moitié, après que son plan de polarisation a subi une rotation de 45° dans le même sens que le rayons émis par le corps 1, vient frapper le premier nicol. La section principale de ce nicol étant perpendiculaire au plan de polarisation, aucune radiation ne le traverse, et nous pouvons renvoyer toute la lumière au corps 2.

"Le corps 2 recoit ainsi trois fois plus d'énergie que le corps 1. [That is, 2 receives the whole of its own radiation and the half of that of 1, while 1 receives only the half of its own radiation.] L'un de ces corps s'échauffera par conséquent de plus en plus aux dépens de l'autre."

Wien then suggests certain ways of escape from this conclusion, but it appears to me that the difficulty itself depends upon an oversight. It is *not* possible to send back to 2 the whole of its radiation in the manner

[1] The italics are in the original. That magnetic rotation may interfere with the law of reciprocity had already been suggested by Helmholtz.

proposed. The second half, which after passage of Nicol 2 is totally reflected at Nicol 1 and then returned upon its course, on its arrival at Nicol 2 is not transmitted (as Wien seems to suppose) but is totally reflected. When again returned upon its course by a perpendicular reflector, and again rotated through 45° by the magnetised medium, it is in a condition to be completely transmitted by Nicol 1, and thus finds its way to body 1, and not to body 2 as the argument requires. The two bodies receive altogether the *same* amount of radiation, and there is therefore no tendency to a change of temperature.

Although I have not been able to find any note of it, I feel assured that the above reasoning was present to my mind when I wrote the passage already cited.

RAYLEIGH.

MARTIN F. WOODWARD.

IN Martin Fountain Woodward, whose untimely death by drowning we recorded in our issue of September 26, science has lost an untiring devotee, zoology a brilliant student and investigator, a teacher whose personal influence and example will live in the memory of those to whom he so willingly imparted knowledge.

M. F. Woodward, younger son of Dr. H. Woodward, F.R.S., keeper of the geological department of the British Museum of Natural History, was born in London on November 5, 1865, and educated at Kensington Grammar School. In 1883 he entered the Royal School of Mines and Normal School of Science as an associate student, qualifying in 1885 with distinction, as the recipient of the Murchison medal and prize of books, for excellence in geology. In zoology he attended the last session's work conducted by the late Prof. Huxley. In both elementary and advanced examinations he headed the pass-list, and showed his power by an achievement in the practical work which so far excelled all precedent that for years his dissection was at Huxley's request kept for use, as an ideal to which the ordinary student might aspire. In this and his class-work combined, Woodward evinced such special aptitude for biological study that Huxley at once appointed him an assistant. In the following year he was made demonstrator of zoology, and in that capacity he continued to labour zealously and with great ability for the remaining seventeen years of his life, inspiring affection and respect in all with whom he came in contact.

With advancing years, Woodward developed a special aptitude for microchemical work and marine investigation. His fame as a preparateur brought to him numerous friends and coworkers anxious to benefit by his assistance and advice, who are to-day unanimous in their admiration of his manipulative skill and mental attainments. His mind was ever clear, his judgment sound, and by his energetic enthusiasm and foresight he was at times directly influential in uprooting error and misinterpretation in their work, thereby earning their lasting gratitude. His leaning towards marine zoology received a welcome impetus in an opportunity afforded him in the summer of 1887, by Mr. W. H. Hudleston, F.R.S., of conducting a dredging trip in the English Channel, at the conclusion of which his efforts elicited the high encomium of his friend. He later spent his summer vacations in marine research, exploring the fauna of the Channel Islands, working at the Plymouth Marine Station, till finally, through the instrumentality of Mr. E. W. L. Holt, whose friendship he made while he was a student in our College, he was enabled to spend his last three vacations at the Marine Biological Laboratory of the Irish Fishery Board, first at Inishbofin and then at Moyard, where he met his death. Published reports bear testimony to the success of his achievements, and in a recent letter the Vice-President of the "Department of Agriculture and Technical Instruction for Ireland," under which the later work was done, has highly eulogised his labours, character, and attainments. Only a few days before his death, Woodward, in a letter to his friends, wrote with delight of a 380-fathoms haul, which had yielded a *Halo-porphyrus*, a large *Pomatomus*, and about 20 Asthenosomas, rare captures for the British Seas. In describing this catch he presented a word-picture worthy his high artistic ability, which, while testifying to his own great enthusiasm, appealed strongly to that of the zoologists to whom it was communicated.

Woodward from time to time published papers on subjects of special study, the outcome of work done in the scanty leisure his official duties allowed. Among the earlier of these is a valuable paper in the Proc. Zool. Soc. for 1892 on the dentition of Hyrax, Huxleyean in its methods and based on the specimens briefly recorded by Huxley in 1863. In this memoir much that was hitherto confusing in the dentition both of *Hyrax* and other placentalia was rendered clear, and through it Woodward was led to an extended inquiry into the genesis and succession of the teeth in the marsupialia, with the result that his published memoirs placed him in the front rank of comparative odontologists. To have revolutionised our conceptions of the incisors of the Diprotodonts, to have shown that the single so-called successional cheek-tooth of the marsupialia is most probably a retarded pre-molar, and to have contributed to the unravelling of the intricacies of the tooth-complex of the Insectivora, is to have essayed a plucky task and to have earned the lasting gratitude of zoologists of all nationalities.

Woodward, true to his family traditions, cultivated a love of the Mollusca, and upon these animals he published a series of most valuable papers, terminating in a well-nigh exhaustive study of the famous *Pleurotomaria*, published in the *Qu. Jour. Microscp. Sci.* for 1891. His papers upon other molluscs were for the greater part contributed to the Proceedings of the Malacological Society, of which he was one of the original members and the secretary at the time of his death. To read these memoirs is to appreciate the fact that Woodward possessed a knowledge of molluscan morphology second to that of no living malacotomist, and his discussion of the affinities of the Monotocardia set forth in his last published paper may be recommended to those who would gauge his reasoning capacity. Upon the Mollusca he had long specialised, and his concluding act as a teacher was a course of lectures at the Royal College of Science which for depth and originality of treatment will be a lasting memorial to his powers to those who were so fortunate as to hear them. They embodied his preliminary notes and ideas for a book he had intended to write, and it is terrible to think that with his death this brilliant achievement has been cut short.

Ever alert for a new observation, Woodward, as opportunity occurred, made public his passing notes. As an example may be cited his intensely interesting discovery of an earthworm possessed of seven pairs of ovaries. He performed a notable task, involving the spare time of three of his best years, in editing the English edition of vols. ii., iii. and iv. of Korschelt and Heider's "Text-book of Embryology," the emendations, curtailments, and annotations which he effected materially increasing the value of the work.

Woodward was always ready to cooperate with friends and fellow workers in anything which would advance our knowledge of the phenomena of life. He leaves behind him a magnificent series of photomicrographs of the fertilisation process in *Ascaris megalocephala*, made from sections which he had prepared, and an extensive series of preparations, drawings, and notes, upon the spermatogenesis of the Mollusca, the rough arrangement of which constituted the closing act of his College life.

On August 2, Woodward, having just recovered from a surgical operation, journeyed to Moyard, in company with his friend Mr. W. Watson, F.R.S., assistant professor of physics in the Royal College of Science, who had before accompanied him on similar occasions. On Sunday, September 15, after spending the day with their friend Mr. Allies, resident land-owner of Inishbofin and other adjacent islands of the Galway seaboard, on the return journey and within sight of land their boat was capsized by a sudden squall. While Watson and the fisherman in charge managed with extreme difficulty to reach the shore, Woodward, though a good swimmer, sank and entirely disappeared, and although every effort was made to recover the body, it was not brought to the surface till September 27.

He was laid to rest on Sunday, September 29, in the peaceful little Protestant churchyard at Moyard, in the presence of his two sisters, Mr. Watson, Mr. Holt, of the Irish Fisheries Board, and a few of his devoted friends. One reflects with sorrow that circumstances should have combined to remove from the world of action before he was thirty-six a man so universally esteemed. We revere his memory as that of an earnest and original worker, loving and sympathetic, whose self-sacrificing nobility of character, critical capacity, and devotion to the cause of science will long be remembered by the many friends who mourn his loss. G. B. H.

NOTES.

THE Harveian Oration of the Royal College of Physicians will be delivered by Dr. Norman Moore on Friday, October 18.

WE regret to have to record the death, at the age of sixty-nine, of M. R. Koenig, of Paris, well-known for his researches in acoustics, light and heat.

THE *Journal of Botany* records the death, from cholera, in India, on September 14, of a promising young botanist, Mr. William West, at the age of twenty-six. Mr. West had passed a distinguished career at the Royal College of Science, where he obtained the Forbes medal for botany, and at Cambridge, though greatly marred by ill health. He had devoted himself chiefly to the study of freshwater algæ, and had gone to India as biologist to an Indigo Planters' Association.

THE ship *Discovery*, engaged on the British exploring expedition in the Antarctic regions, arrived at Cape Town on October 3. After coaling the *Discovery* will proceed to Simons Bay and thence direct to Lyttelton, not calling at Melbourne in order to save time.

SPEAKING at Upsala to the Swedish Geographical Society on Wednesday of last week, Prof. Nordenskjöld announced that the Swedish South Polar Expedition would be ready to start soon after the 8th inst. After reaching the Falkland Islands, where a depôt will be established, the expedition will continue its voyage southwards. After making their way as far south as possible, the explorers will look for a spot suitable for wintering in. The ship, with three geologists on board, will then return to the Falkland Islands, whence scientific excursions will be conducted throughout the winter. The expedition will probably return to Sweden at the beginning of 1903.

IT is announced in the German semi-official newspapers that the German Government has again placed at the disposal of the Chinese Government the astronomical instruments which were removed from Peking by the German contingent. The Chinese Government has replied that in view of the inconvenience and difficulties which would be involved in conveying the instruments back to China and placing them in their former position it declines the offer.

THE resignation of Dr. Purser, King's Professor of the Institutes of Medicine in the School of Physic, Trinity College, Dublin, is announced. In 1899, on the completion of the twenty-fifth year of his professorship, Dr. Purser's past pupils, in token of their appreciation of him and his services, founded the "John Mallet Purser Medal" for award yearly in the School of Physic to the candidate who obtains the highest marks in physiology and histology at the Half M.B. examination. Prof. Purser's decision has been arrived at, not on account of ill-health or failing energy, but, as the *British Medical Journal* understands, in order that with the increased laboratory accommodation which the Board of Trinity College has provided for the teaching of physiology and histology his successor may have the advantage of equipping the laboratory and organising the work on the more extended basis.

A REUTER telegram, dated October 7, gives further particulars as to the progress of the campaign in Freetown, Sierra Leone, of the Liverpool School of Tropical Medicine against mosquitoes. Up to September 17, 6500 houses had been cleared by Dr. Logan Taylor and his assistants of the receptacles in which the Culex mosquitoes breed, and draining operations against the Anopheles mosquitoes are being pushed forward as much as the rain will allow. In addition to fifty other men employed on the operations of the expedition, two men are specially employed to look constantly after the centre of the town, where the offices, warehouses, and European houses are. The Governor, Sir Charles King Harman, is giving every assistance. Dr. C. W. Daniels, medical superintendent of the London School of Tropical Medicine, who was attached to the expedition and has been studying Dr. Taylor's work at Freetown, has now returned to England. In a report of his observations, addressed to Major Ross, he says:—"In my opinion your efforts have already been crowned with a large degree of success, as there has been a noteworthy diminution in the number of the two first genera of mosquitoes, Anopheles and a kind of Culex, found in the houses. The number o preeding ground has been enormously diminished."

AT the International Congress of Physiologists recently held at Turin a noteworthy tribute of esteem was paid to Sir Michael Foster on his resigning the presidency to his successor, Prof. Angelo Mosso. This consisted in the presentation of a plaque, of which we reproduce (from the *British Medical Journal*) the inscription, granting him the unique distinction of Honorary Perpetual President of the Congress. The wording on the plaque is as follows:—

CONVENTUS PHYSIOLOGORUM INTERNATIONALIS QUINTUS HOC DIE VIRUM ILLUSTRISSIMUM SENIOREM

MICHAELEM FOSTER

PRAESIDEM HONORARIUM PERPETUUM CONVENTUUM PHYSIOLOGICORUM INTERNATIONALIUM CREAVIT

CONVENTUS NOSTRI GRAVISSIMI VIRI DOCTI AUCTORITA TE EIUSDEMQUE STUDIO STRENUO INTEGRE FLORENT FOSTERO CATALOGUM SCIENTIARUM NATURALIUM QUO NEMO IAM NATURAE INDAGATOR CARERE POTEST DEBEMUS GRATIA SIT HONOSQUE PROPUGNATORI NOSTRO! NOMINE CONVENTUUM PHYSIOLOGICORUM INTERNATIONALIUM CONVENTUS QUINTI PRAESES

ANGELUS MOSSO.

AUGUSTAE TAURINORUM AD XV KAL. OCT. A. MCMI.

THE Hanbury gold medal for 1901 was presented on the 1st inst. to Dr. George Watt by the president of the Pharmaceutical Society. This medal, which was established as a memorial to Daniel Hanbury, is awarded biennially for high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs, and the council of the Pharmaceutical Society are the trustees of the memorial fund.

The sixtieth anniversary of the foundation of the Pharmaceutical Society has just been celebrated by the presentation of a badge of office to be worn by successive presidents of the Society. An illustration of the badge appears in the current issue of the *Pharmaceutical Journal*.

An expedition is about to be despatched to Christmas Island, under the auspices of the London School of Tropical Medicine, for the purpose of investigating beri-beri. The leadership of the expedition has been accepted by Dr. H. E. Durham, who will join the s.s. *Islander* at Port Said on or about October 16. The inquiry will probably extend over a period of twelve months.

Sir Francis Lovell, Surgeon-General of Trinidad, will, according to the *Hospital*, leave England during the present month on a mission to tropical and other countries on behalf of the London School of Tropical Medicine. Lord Brassey will preside at a meeting at the Royal United Service Institution on October 16 to deliver an inaugural address on the opening of the third winter session of the school and to give a send-off to Sir F. Lovell.

The return of Dr. H. F. Knowlton, of the U.S. Geological Survey, from a trip through the John Day Basin, Oregon, is noted in *Science*. The special object of the expedition was to secure collections of fossil plants, and of the vertebrate fauna of the neighbourhood, and much valuable material has, it is reported, been obtained.

Magnetic observatories are being established under the auspices of the U.S. Coast and Geodetic Survey at Sitka, Alaska and in Honolulu.

A course of six popular science lectures for young people, entitled "Peeps into Nature's Secrets," will be delivered at the Kensington Town Hall on October 17, 24, 31, November 14, 28, and December 5. Particulars as to the subjects of the lectures and the names of the lecturers are to be found in our advertisement columns.

Free popular science lectures will be delivered in the museum of the Whitechapel Free Library as follows:—November 12, at 8 p.m., "The Faroe Islands and Iceland," by Prof. C. Lloyd Morgan, and December 11, at the same hour, "The Instincts and Intelligence of Animals," by Lord Avebury. In connection with the course, Dr. T. K. Rose lectured on Tuesday last on "Alloys, and what we know about them."

The *Athenaeum* states that the Berlin Königliche Akademie der Wissenschaften and the Danish Academy at Copenhagen have decided to prepare a collection of all the medical works of antiquity under the title of "Corpus Veterum Medicorum," and will cause a thorough examination to be made of all libraries, Oriental and European, which are likely to contain MSS. dealing with medical subjects.

A meeting of the Royal Microscopical Society will be held on Wednesday, October 16. A paper on the fungi found on germinating farm seeds will be read by Miss A. Lorrain Smith; it will be preceded by an exhibition of mounted specimens of marine zoological objects by Mr. C. L. Curties.

A very successful meeting of the British Mycological Society was held at Exeter from September 23 to 28, when several scarce specimens of fungus were obtained. At the evening gatherings papers were read by the president (Prof. H. Marshall Ward), Miss A. Lorrain Smith, Dr. C. B. Plowright, and Mr. B. T. P. Barker.

The Paris correspondent of the *Times* states that the French Post Office has decided to print upon letters the hours of collection numbered, as in Italian and other railway time-tables, from 1 to 24, or rather to 0, which will signify midnight.

According to the *Lancet*, the New York City Board of Health has adopted resolutions to the effect that the officers of "public institutions, hospitals, homes, asylums, &c., be required to report all cases of malarial fever which come under their observation, giving the name, age, sex, occupation and present address of the patient," and "also information as to whether the attack is a primary infection or a relapse, and the address where the disease was probably contracted"; also "that all physicians in the city of New York be requested to furnish similar information in regard to patients suffering from malarial fever under their care."

Dr. Adolph Gehrmann, director of the Chicago City Laboratory, and Dr. W. A. Evans, of the Columbus Medical Laboratory, have devised a plan of investigation, the main feature of which is to make the experiment with lupus. They hold that just as satisfactory a test can be obtained by inoculating the skin of a human being with the bacillus from an animal as could be got from experiments with pulmonary tuberculosis, with the great advantage that there is no risk to life. Preparations are being made for the experiments, and two persons have already consented to be inoculated.

Scientific visitors to Ceylon, and botanists generally, will be interested to know that a small residential laboratory has been opened at the Hakgala Botanic Gardens, near Nuwara Eliya, at an elevation of 5600 feet above sea-level. The laboratory is a branch of the Peradeniya institution, described in Nature, November 9, 1899, and consists of a small building containing a working room 21 feet × 12½ feet, a living room, two bedrooms, kitchen, &c. The climate is temperate, fires being required in the evenings at least. The botanic garden itself is very beautiful, and occupies an unrivalled position for the study of equatorial hill vegetation, for on one side there are jungles stretching for 25 miles or more into the wet region of the hills, on the other grassy plateaux (patanas, *cf.* Pearson in *Journ.* Linn. Soc., 1899), reaching for an equal distance into the dry region, and extending from 3000 to 7000 feet above sea-level. The garden itself contains both jungle and patana reserves of several hundred acres.

The *Daily News* of October 7 contains a long interview with Mr. Cheesewright on the scheme for constructing a high-speed electric railway between London and Brighton. The system proposed to be adopted is not described, but it is stated that the monorail, of which so much has been heard of late, is not to be used and that each car will carry its own motor. A speed of nearly 90 miles an hour is aimed at, so that the whole journey of 47 miles will only occupy 32 minutes. This high speed is to be made possible partly by having no intermediate stations, and partly by avoiding all curves and gradients by tunnelling wherever hills occur along the route. In addition to the benefit conferred by a half-hourly service of express trains, the public is to be attracted by the cheapness of the fares. The Bill will, without doubt, meet with serious opposition in Parliament from the London, Brighton and South Coast Railway, but we wish the promoters of the scheme every success. We feel sure that the public have only to be taught, by a few striking examples, the immense improvements that electric traction can effect in railway travelling to insist upon its adoption in suitable cases by our existing steam railroads. It is only by healthy competition of the kind that such railways as this will introduce that it will ever be possible to eradicate the often very primitive ideas of comfort and convenience that seem to be possessed by the great railway monopolists; and we hope, and believe, that it will be the function of electric traction to produce as great a change in the comfort of travelling in the present century as did steam railways in that which has just closed.

THE *Electrician* announces that the Hon. A. Lyttelton has been appointed by the Board of Trade as arbitrator to settle the dispute between the Metropolitan and District Railway Companies as to the electrical equipment of the Inner Circle. The disagreement has been long and bitter, and, as the *Electrician* points out, has not only unnecessarily delayed the improvement of the Inner Circle, but has also created an impression that electrical engineers are undecided upon the question of the most satisfactory system of electric traction. That this is true in its broadest sense is no doubt the case, but there are many thoroughly satisfactory systems from which to choose, and it is to be hoped therefore that it will not now be long before one is selected and the alteration of the Inner Circle begins in real earnest.

THE New York *Electrical World and Engineer* for September 28 contains a long article descriptive of the Cooper-Hewitt mercury vapour lamp. A brief description of this lamp was given in NATURE (May 9, p. 39) at the time it was first exhibited in America. The present article is founded on the contents of ten patents just issued to Mr. P. Cooper-Hewitt, and describes in considerable detail the construction and manufacture of the lamps. The chief difficulty met with is apparently in starting the lamp; it is found, however, that a small amount of sulphur introduced into the tube (as sulphide of mercury) makes it much easier to overcome the initial high resistance, but even with this addition a transformer or induction coil is still needed. Once lighted, the lamp is said to burn steadily on 100-volt or 200-volt circuits. The unpleasant colour of the light from mercury vapour can be cured, according to the inventor, by the use of nitrogen in the lamp, this adding the necessary red rays. When originally iutroduced, the consumption of energy was given as only half a watt per candle, a value which is astonishingly small. We await, therefore, with the greatest interest some account of the practical performance of the lamp; unfortunately, it is often a big wait from the patent to the commercial lamp, and it can only be hoped that in this case the time will not be over long.

THE general report on the operations of the Survey of India for the year 1899–1900 shows that the total area triangulated was 41,110 square miles, including 16,000 square miles triangulated in connection with reconnaissance surveys, and valuable scientific observations were effected in the determination of latitudes. The Government of India, in a resolution reviewing the report, notice with interest the large addition to the geographical knowledge of Yunnan and the north-eastern frontier, and acknowledgment is made of the efficient way in which the work of the department has been carried on.

SOME stir has been made in connection with "Kent coal" by the proving in another boring at Dover of certain coal-seams which in reality were discovered some twelve years ago. The original coal-boring was commenced as far back as 1886, and a depth of more than 2000 feet was ultimately reached. The fact that another boring in the immediate neighbourhood has been carried to a depth of 1194 feet is of no particular importance. What is required is that the shaft should be completed down to the workable coal, and the information with regard to this (given in the *Financial Times* of October 4) is that it is hoped to bring up coal "in about fifteen months' time." That the existence of the "coal-field" has been proved "beyond reasonable doubt" will not be questioned; the extent of it remains to be proved. There may be small isolated tracts of faulted Coal Measures, or a continuous field extending ten miles or more.

THE Geological Survey of Egypt has just published an account of Dakhla Oasis by Mr. Hugh J. L. Beadnell. This oasis lies to the south of that of Farafra, an account of which was previously published (NATURE, August 8). It is by far the most important of the four great oases of the Libyan Desert, on account of the number of its inhabitants, the extent of its cultivated lands and palm groves, and the copiousness of its water-supply. The water-supply is derived from an underground bed of sandstone, which is never visible. This is overlain by a bed of red clay and underlain by black clay. The water appears to flow to the surface entirely through artificial wells and bore-holes, ancient and modern. Many of these artesian wells were made during the Roman occupation of the country, some are still in thorough working order, and they are as deep as those bored recently, about 140 metres. The temperature of the waters varies from 78° to 102° F., the heat being due to the depth from which they arise and being modified by local conditions. The water-bearing strata belong to the Nubian Sandstone series (Senonian or Upper Cretaceous). They are overlain by a great thickness of soft Danian beds capped by hard white chalky (Danian) limestone. After the hard capping had been eroded further waste proceeded rapidly, and the formation of great depressions, without drainage outlets, has been due mainly to wind erosion.

THE eruptive rocks of the neighbourhood of Ménerville, Algeria, form the subject of an elaborate essay by MM. Louis Duparc and Francis Pearce, to which Dr. E. Ritter has contributed particulars of the geological structure of the country (*Mem. de la Soc. de Physique et d'Hist. Nat. du Genève*, xxxiii. part 2, 1901). Special attention is given to the liparites and dacites and to their relations with the granitoid rocks (tonalites and micro-tonalites). In the same volume, M. P. de Loriol describes some new echinoderms, including *Pygurus* from Cenomanian and *Echinolampas* from Oligocene strata, and a number of recent species of *Astropecten*, &c., from various parts of the world.

IN the *Proceedings* of the Royal Society of Victoria, vol. xiv. part 1 (August, 1901), geology dominates. Various trachytic rocks are described by Mr. J. Dennant, while the older Tertiary mollusca are in course of description by Mr. G. B. Pritchard, who contributes an account of the lamellibranchs (part 2). There is also a short article by Mr. T. S. Hall on the stages of growth in modern trigonias, which exhibit considerable variation both in the shape of their shells and in their ornament.

IN 1895, a gravitational survey of the kingdom of Württemberg was commenced, and ten stations for the purpose were selected in the first instance on the meridian of Tübingen. The first definite results were obtained in 1899. Dr. K. R. Koch now describes the results of redeterminations made by pendulum methods in 1900, and publishes an account of the methods adopted for eliminating errors of experiment and observation. With the exception of one station, the observations of 1899 and 1900 agree to within about two millionths of the observed values.

A DISTRICT which is free from malaria, in spite of the fact that species of *Anopheles* are abundant and all the conditions are favourable to the occurrence of this fever, forms the subject of a paper by Dr. Grassi in the *Atti dei Lincei*, x. 6. The district is that of Massarosa, about eight kilometres from Viareggio. This district is largely given over to rice cultivation, and, among other noteworthy points, Dr. Grassi finds (1) that malaria formerly existed in Massarosa, but has now practically died out; (2) that its decrease has taken place concurrently with the extension of the rice plantations, notwithstanding that these form a breeding ground for the mosquitoes; (3) that the mosquitoes in question have not acquired any special immunity from malaria, seeing that they have been artificially infected by being allowed to bite a malarial patient; (4) that many of the inhabitants spend a portion of the year in infected districts where they frequently take the disease, showing that they likewise are not immune. The only conclusion which Dr. Grassi can draw is that malaria does not necessarily occur even in districts favourable to its propagation, and hence he thinks it probable that the disease may be easy to stamp out in infected districts, especially with the systematic use of wire mosquito nets. But there is quite a possibility that the district of Massarosa may be visited at some future time by a scourge of malaria.

A REPORT on the work done at the observatory of Catania in connection with the international photographic survey of the heavens is contributed by Prof. A. Riccò to the *Atti dei Lincei*, x. 5. Among the difficulties to be contended against in the work, that of developing the negatives in the hot climate of Catania may be noted. Since the beginning of 1897, the total number of celestial photographs taken was 430, including 250 for the catalogue, 78 of the zone traversed by the planet Eros, 6 of the new star in Perseus, 3 of the occultation of Saturn, and 6 of lunar eclipses. In addition, the writer and Prof. Tacchini took 66 photographs on the occasion of the eclipse of May 20, 1900, in Algiers. A number of measurements, embracing 22,435 stars, have been made on the plates by Signori L. Franco and M. Massa, and reduced by Signor Mazzarella. Among the calculations made by Prof. Boccardi, with the assistance of Signori Traversa and Taffara, we note the construction of tables for the differences of precession depending on the different constants of Struve and Newcomb, catalogues of 2200 stars taking account of proper motion and of the constants of Newcomb, and the reduction to the equinox of 1900 of 8000 stars of the zone studied at Catania. Prof. Riccò hopes shortly to commence the publication of the catalogue.

THE *Century Magazine* for October contains a short article on "How to cross the Atlantic in a Balloon," by Prof. Samuel A. King, with an introduction by Prof. Cleveland Abbe. Prof. King deprecates the attempts to solve a problem of this character by means of flying machines or mechanically propelled balloons, and thinks that the secret of success lies in mastering the problem of maintaining the ordinary spherical balloon at any required height by the aid of the drag rope or similar appliances. The author also points out the necessity of overcoming the propensity of the balloon to rise and fall with varying temperature, and suggests the use of a hood as a protection from solar radiation. With proper precautions, Prof. King considers a Transatlantic balloon voyage now quite within the range of feasibility.

WE have received a copy of the Results of the Magnetical and Meteorological Observations made at the Royal Alfred Observatory, Mauritius, in the year 1899. Some of these results were alluded to in our notice of the Annual Report (NATURE, June 6, p. 135). Magnetic disturbances occurred on nineteen occasions. A list of them is given in an appendix; the principal were: January 28–29, February 12–13, May 3–5, and September 26–27. The mean declination in the year 1899 was 9° 32′·89 west. There were only four tropical cyclones in the South Indian Ocean during the year, viz., on January 1–8, March 3–8, November 30–December 3, and December 10–16. This cyclone passed over Mozambique on the 17th; the length of its path (more than 3000 miles) has seldom been exceeded in the Indian Ocean. The barometrical readings at the Observatory were appreciably affected at a distance of more than 800 miles. Twenty-seven seismic disturbances were recorded at the Observatory during 1899. The small number of recorded earthquakes at Mauritius as compared with other countries is noteworthy.

THE origin and birthplace of the Proboscidea have long been a puzzle to students of evolution and distribution, the mastodons suddenly making their appearance in the middle part of the Miocene, without our having hitherto had the slightest clue as to their connection with more generalised types. The puzzle has, in a great degree, been solved by Dr. C. W. Andrews, of the British Museum, who, during a recent visit to Egypt, was fortunate enough, while travelling in the Fayum district in company with Mr. H. J. L. Beadnell, to come across two Tertiary deposits which have yielded a previously unknown vertebrate fauna, a part of which is described by Mr. Andrews in the September issue of the *Geological Magazine*. From the upper beds, provisionally regarded as Lower Oligocene, were obtained remains of a small mastodon-like animal (Palæomastodon), differing from Mastodon by the simpler last molar and by having five pairs of cheek-teeth simultaneously in use. The other remains are from a lower horizon, perhaps Upper Eocene, but possibly rather older. Most remarkable is a primitive proboscidean (Mœritherium), with a nearly full series of front and cheek-teeth, the latter being of a generalised Ungulate type. That this animal is an ancestor of the mastodons and elephants may be inferred from the enlargement of the second pair of incisors in both jaws and the small upper canines. All the six pairs of cheek-teeth were in use at the same time. More problematical are the affinities of a huge Ungulate described as Bradytherium. From the same beds Mr. Andrews obtained a Zeuglodon, previously described by Dames, and also a Sirenian, probably identical with Owen's Eotherium. A description of the reptiles is promised later. The importance of the discovery can scarcely be overestimated. It is noteworthy, in connection with a recent theory, that the fauna is situated in the Holarctic, and not in the Ethiopian, region.

IN their Report to the forthcoming anniversary meeting, the committee of the Natural History Society of Northumberland, Durham and Newcastle-upon-Tyne have to deplore the deaths of three prominent members, namely Lord Armstrong, Dr. Embleton and Mr. R. Howse, the last of whom served the Society so well for many years as curator of its valuable museum. We learn that Mr. E. L. Gill, who has been appointed to succeed Mr. Howse, speaks well of the general state of the collections. The finances of the Society, we are glad to hear, continue in a satisfactory condition.

THE *Bulletin* of the Agricultural College at Tokyo contains a capital investigation by Mr. U. Suzuki on the formation and distribution of theine in the tea plant. The seed contains no theine, but this alkaloid appears during germination even in the dark. The roots and stem contain a moderate amount of theine, the bark very little. It occurs in greater quantity in the dormant leaf-buds, and reaches its greatest development in the young leaves, in which 20 per cent. of the nitrogen is sometimes in this form. In old leaves the quantity is greatly diminished. The theine appears to be specially localised in the epidermis of the leaf. Mr. Suzuki has another paper in the same periodical, on the occurrence of organic iron compounds in plants. The seeds of *Polygonum tinctorium* and *Indigofera tinctoria* yield an ash containing 12 per cent. of ferric oxide. The whole of this iron exists in the seed in organic combination, apparently as a ferro-nuclein. The greater part of the iron in plants probably exists in a similar state of combination.

THE decorative symbolism of the Arapaho, a tribe of Plain Indians belonging to the Algonquin stock, is the subject of an essay by Mr. A. L. Kroeber in the *American Anthropologist* (N.S., vol. iii. 1901, p. 308). In all the examples referred to by the author there is, as there is practically everywhere else, a well-developed symbolism and a conventional decoration, which exist not side by side but in each other. Most primitive decoration, no matter how geometric or simple, has significance, and thus is, visually or ideographically, realistic. This fusion of two differing tendencies (symbolism and decoration) is a rule practically without exceptions. It is universal, because it is necessary. At times, as in European civilisation, the two tendencies become more separated, but the more primitive a people is, the more intimately fused in its art will these two tendencies be. Other tendencies also are still combined with these two in a sufficiently early and rude condition of society. The symbolism of the Arapaho is as ideographic as it is realistic, and is as much a primitive method of writing as it is of artistic representation. The author argues that it is incorrect to assume that symbolism, or any other single motive, accounts for the origin of a design. Thus we come to the conclusion that all search for origins in anthropology can lead to nothing but wrong results. The tendencies referred to are at the root of all anthropological phenomena. Therefore it is these general tendencies, more properly than the supposed causes of detached phenomena, that should be the aim of investigation.

THE additions to the Zoological Society's Gardens during the past week include a Black Kite (*Milvus migrans*), European, presented by Mr. J. B. Thornhill; a Diana Monkey (*Cercopithecus diana*) from West Africa, a Yellowish Capuchin (*Cebus flavescens*) from South America, a Fournier's Capromys (*Capromys pilorides*) from Cuba, a Small-clawed Otter (*Lutra leptonyx*), two Bungoma River Turtle (*Emyda granosa*), a Ring-necked Parrakeet (*Palaeornis torquatus*) from India, a Vulpine Phalanger (*Trichosurus vulpecula*) from Australia, two Yellow-winged Parrakeets (*Brotogerys virescens*) from Brazil, a South Albemarle Tortoise (*Testudo vicina*) from the Galapagos Islands, eight Wrinkled Terrapins (*Chrysemys scripta rugosa*) from the West Indies, a Grey Monitor (*Varanus griseus*) from North Africa, a Razorbill (*Alca torda*), British, deposited; a Grey Squirrel (*Sciurus cinereus*) from North America, a Mouflon (*Ovis musimon*) from Sardinia, a Common Rhea (*Rhea americana*) from South America, purchased; eight Golden Orfe (*Leuciscus idus*) from European fresh waters, purchased.

OUR ASTRONOMICAL COLUMN.

EPHEMERIS OF ENCKE'S COMET (1901 *b*).—Herr Ch. Thonberg gives a further ephemeris for following this comet, in *Astronomische Nachrichten*, Bd. 156, No. 3740.

Ephemeris for 0h. Berlin Mean Time.

1901.	R.A. h. m. s.	Decl. ° '
Oct. 10	14 19 46	−20 11·2
12	32 42	21 22·9
14	45 20	22 28·0
16	14 57 42	23 26·9
18	15 9 46	24 19·8

30	16 15 50	−27 52·5

NEW ALGOL-TYPE VARIABLE, 78 (1901), CYGNI.—Mr. A. Stanley Williams has detected variability in the star, whose approximate position is:—

$$\left.\begin{array}{l}\text{R.A.} = 20\text{h. } 18\text{m. } 4{\cdot}0\text{s.}\\ \text{Decl.} = +42^\circ\ 46'{\cdot}4\end{array}\right\}(1855).$$

The measures of brightness were made from photographs obtained with a 4·4-inch portrait lens. Normally the star is about 10th magnitude, falling almost to 12th magnitude at mininum. It appears about a magnitude below normal brightness on a photograph taken 1900 October 21, 13h. 0m. to 13h. 50m. G.M.T.; and minima have also been visually determined on the following dates:—

	h.	m.
1901 Aug. 24	14	27 G.M.T.
Sept. 7	9	43
,, 14	7	29

From these data the elements of the star's variation are:—

Minima = 1901 Sept. 7d. 9h. 43m. + 3d. 10h. 49m. E.

For about 3d. 2h. 19m. the star remains constant at 10·0 magnitude. It then diminishes in 3h. 30m. to 12 magnitude, at which it remains for 50m. Recovery to 10 magnitude occurs in 4h. 10m., the whole change occupying about 8h. 30m. (*Astronomische Nachrichten*, Bd. 156, No. 3740).

PHOTOGRAPH OF THE SPECTRUM OF LIGHTNING.—Prof. Pickering announces that a successful photograph of the spectrum of a lightning flash has been obtained recently at the Harvard College Observatory. The spectrum showed a complicated series of bright lines which have as yet not been individually recognised. No information is at present extant as to the instrument with which this interesting photograph has been taken, but it is to be hoped that the scale is sufficient to ensure accurate determinations of wave-length. For some years back attempts have been made at the Solar Physics Observatory at South Kensington to record the lightning spectrum, using both prisms and gratings in conjunction with short-focus cameras of varying size. Up to the present time, however, no success has been attained, and it is with the greatest interest that the publication of further details from Prof. Pickering will be awaited.

THE ROYAL COLLEGE OF SCIENCE AND THE UNIVERSITY OF LONDON.[1]

I AM sorry to have to sound at the outset a note of sadness. We little thought when the end of the session brought release for us all that before we could meet again death would intervene to prevent one of our number from joining his colleagues and friends at the reassembly. It may not be known to every one present that a deplorable accident has deprived the College of one of the most brilliant and popular of the junior members of the staff. Mr. Martin Woodward, demonstrator of zoology, was the younger son of Dr. Henry Woodward, the eminent keeper of the geological department of the British Museum, who is a personal friend of many of us and respected by everybody. United as father and son were, not only by ties of affection but by constant companionship in their scientific pursuits, we can only guess and I cannot express, the severity of the father's loss. All we can do on this sad occasion is to offer to the family of our departed friend our most heartfelt sympathy. Mr. Woodward entered the College as a student in 1882 and gained the Murchison prize and medal. He was appointed demonstrator by Prof. Huxley in 1885, and has since that time worked under the direction of Prof. Howes. Most of us deplore the loss of a genial, kindly and accomplished friend, but science too is the poorer by this unhappy event, for Woodward was well known as a zoologist, and his extensive knowledge, skill as a manipulator and scientific enthusiasm seemed to promise a high place for him among the biologists of his time.

The next announcement that I am permitted to make is of a more cheerful character. Dr. Stansfield, of the metallurgical division, has been appointed professor of metallurgy in the McGill University, Montreal. All students who have come under Dr. Stansfield's influence will, I believe, gladly unite with his colleagues in wishing him a long, happy and distinguished career in his new home across the sea.

By this time it is probably known to most of the students assembled here that the session now gone has seen the last of two of the most eminent members of the staff as professors in the College. In Sir Norman Lockyer we are losing an investigator of the first rank who may be said to have created a branch of science out of the results of his own researches. But apart from his labours in astronomical physics, I feel that the scientific part of the community owes much to Sir Norman Lockyer for the energy with which he has, on so many occasions, defended the cause of science. Whenever a question has arisen of public opinion or public policy involving the position of science, or of scientific men, he has always sounded the right note. You will, I am sure, join with us his colleagues on the council of the

[1] Address delivered at the opening of the Royal College of Science, October 3, by Prof. W. A. Tilden, F.R.S.

Royal College of Science in offering on this occasion of severing an official link an expression of our earnest wish that he may enjoy many years of health and undiminished strength to carry forward those researches which have made the name of Lockyer famous throughout the civilised world. Prof. Rücker has been called away to occupy the high position of principal of the reconstituted University of London, concerning which I shall say a few words presently. It is difficult to express the profound sense of loss with which I refer to the removal of Prof. Rücker. The members of the College have only the satisfaction of knowing that among their number was found the *only* man who seemed to possess the qualifications requisite for this difficult and arduous position. We also have reason to hope that the association of the College with the University will afford opportunities for the exercise of his friendly cooperation and advice whenever they are required in the work of the College which he has served so long and with so much advantage to all good students.

Days like this are milestones on the road of life for all of us—for you students marking very early stages of the journey—for some of us pretty far advanced toward the end. The metaphor suggests that those of us who have travelled in advance may have something useful to say to those who come after. But I am not going to offer much in the way of advice, because my experience tells me that it will be only very sparingly accepted. After all, the road which you have to follow is not the same, things are altered since *we* passed that way, times are changed, and even if it were not so the spirit of each succeeding generation appears to be unwilling to blend itself with the spirit of the past. The instinct of the young is always to try everything afresh and make up the sum of their own experience, and to regard with suspicion everything which the seniors have to say. But I do not seriously blame them. If it were not thus the world would soon be too wise for happiness, the sense of adventure would no longer brighten the springtime of life which "sicklied o'er with the pale cast of thought would lose the name of action."

Apart from the advice which it is my custom to address to my own class on the conduct of their studies, all I desire to say to the students here can be expressed in a few words. Do not suppose that we seniors are indifferent to your fortunes, to your struggles and successes or failures. On such a day as this we rejoice with those who have reason to rejoice—the winners of prizes and rewards. We would gladly be among you as equals or competitors; we think of our own time and the happiness of something attempted, something done. Go on and prosper. To the newcomers whom we welcome to-day, we wish a like success in the years which are to follow. But it must not be forgotten by them that this demands effort, strenuous and sustained effort. It will not be enough to enter the College every day at a few minutes after ten and leave it at a few minutes before four, and though I do not advise midnight oil, I do venture to say that the chief purpose of the Royal College of Science is not to provide a pleasant kind of club for a few privileged young persons at the expense of the Government or of their own parents and friends.

Aut disce aut discede ought to be written up here as it is in another place.

The third course hinted at on that celebrated notice board is not available here. So you must understand that there are but two alternatives recognised among us—either learn or leave the place.

Independently of the circumstances to which I have already referred as marking in a special way the opening of this present session, there is another subject which must before long assume a position of great importance to us. This College is a recognised school of the new University of London, the majority of the staff are recognised teachers, and those students who choose may become matriculated *internal* students of the University. We cannot yet see clearly to what extent this association will influence our work. We hope for the best; but I think we shall all be agreed that we shall not welcome any changes which will not enable us to live up to the splendid standard of the traditions of our College. Some modifications of detail are, no doubt, from time to time desirable, but we cannot have the standard of attainment and of original work lowered to suit the arrangements of some other institution, however influential.

As it is probable that many of you have not had occasion to consider the subject of the constitution and work of the University, I will venture to submit a few thoughts connected with the subject.

I wonder whether any of you have formed an idea of a university so as to be able to define it. Many people think a university is a place where you may get a degree; a few think it is a place for instruction of a professional or technical kind, still fewer think it is a place for research. An eminent member of the present Government made a speech only a few weeks ago in which at the outset he promised to define a university. In the end, however, he did not supply a definition, but he expressed, certainly very clearly, what in his opinion a university ought to do.

Mr. Chamberlain's view is that a university should do four things—it should teach, it should examine, it should add to knowledge by research, it should show the applications of knowledge. A pretty extensive programme surely!

Cardinal Newman's definition—"A place of *teaching* universal *knowledge*"—does not seem to imply so much, because he almost immediately adds that its object is, *inter alia*, the diffusion and extension of knowledge rather than the advancement. "If, he says, its object were scientific and philosophical discovery, I do not see why a university should have students." ("The Idea of a University," preface).

I will venture a new definition. I should say a university is a place of higher education for those who are qualified by nature to profit by it. And I say that deliberately, holding the opinion as I do that it is not advisable to give more than elementary education to everybody, nor to encourage young people indiscriminately to enter upon a university course. An enormous amount of educational power is now wasted in trying to give a training to intellectual faculties which do not exist, for Providence has not given brains equally to everyone, and many a boy and girl now forced by parents or circumstances to the study of books would be much happier and more useful members of the community if they were taught to lay bricks and to sew and cook and wash, and do these necessary things *well* which are now done badly. This, of course, is not the business of a university, but if the university can so arrange its tests, whether by examination, or in some other way yet to be devised, as to prevent any large number of weaklings from entering upon the university curriculum, it will be doing a kindness to the rejected and a service to the rest of the world.

The new University of London is to be a place of education, we are told, and no longer only a system for testing knowledge got anyhow and anywhere. Its business is to prepare its students for the world. I hold strongly to the view that the *primary* business of a university is not to provide technical instruction from the outset, but to provide those conditions which will help to convert *the boy* into *the man*, and so to prepare him by the cultivation of his faculties that he is then ready to receive instruction in any profession or pursuit which may be marked out for him by his own special gifts or opportunities. All your bachelors, whether in arts or sciences, should be merely well-educated young people with brains. If the programme at school and college has been properly laid out, they cannot have had time to have made much progress in technical work. This does not shut other doors into the professions. A man may become a doctor, a lawyer, an engineer or a chemist without going near the university, but the way through the university must, if things are properly ordered, be always the way chosen by the best students. What I fear is a continuance and increase of the confusion between the processes of education which properly belong to the university and the process of instruction in useful arts or applied science which belongs to the technical school, or, if you please, to the more advanced stages of the university curriculum. Some confusion is inevitable in consequence of the existence from early times in the history of universities of the faculties of theology, law and medicine which are necessarily connected with professions. But in a new university tradition should not be allowed too prominent a place.

In the faculties of engineering and commerce which are to be established it will be disastrous to the cause of higher education if technical practice is to be received as an equivalent for studies which contribute to culture, style and character.

I dissent altogether from the view which seems to be held by some people that the sooner a boy gets to things which will be connected with his future business the better. Doubtless circumstances compel the adoption of this course in some cases, but it is not one which ought to receive the sanction of the university.

The confusion of education with instruction, the mixing of preparatory with professional studies, also leads to much waste of time. All preparatory studies ought to be over by the age of twenty-one, and in some cases even sooner. A young engineer ought not at that age to be learning the physics and chemistry and mechanics, the principles of which he certainly requires for use, but should be free to work at his engineering and what pertains directly to it.

We may hope that the university will provide such a liberal programme that there may be many avenues to the same degree suitable to the needs and circumstances of different classes of students. By this I mean that there should be a very free choice of languages and sciences; and I should exclude altogether from the early stages of a student's career commercial and technical subjects which, however practically important they may be, should only be taken up after the first degree, B.A. or B.Sc., has been reached, and the time for concentration has come.

As to the entrance or matriculation examination, much difference of opinion exists. But whether a classical language be insisted upon or not, and whether one or more modern languages be required, seem to me to be questions far inferior in importance to the requirement that every student admitted to the university should have been trained as far as he has gone in scientific method. This does not mean that he should be acquainted with any particular branch of science, but that by means of scientific study he should have been taught to use his eyes so as to see things clearly, and should have been made to understand the nature and the right use of evidence in coming to any conclusion. This cannot be done by literary study alone, and if not begun early in life will scarcely be accomplished later on.

An educated man must have not only thoughts, but language by which he may express his thoughts intelligibly and with such brevity or fulness as befits the occasion or the nature of the subject. He *must* speak and write his own language correctly. How much more should be required by the university I have no time to consider now, but I think no man of active mind will be content with translations of the literature or even of the scientific treatises of other countries.

The university is a place of education *primarily*, as I have said; but it should also be a place for research, and I will try to say why.

It is not, I think, the first business of a university to make new knowledge for the sake of the knowledge, but it is indispensable to all systems of advanced instruction that students should be associated with teachers who are daily engaged in the endeavour to penetrate by new ways into the regions which lie beyond the boundaries of existing knowledge. In no other way can the teaching of the university be preserved both fresh and free from error. Moreover, it is impossible to arrest the progress of discovery, which will go on elsewhere, however it may be ignored by the university, and how is it to keep abreast of the knowledge of the day except by taking part in the process of making it? Fortunately, the statutes framed by the commissioners distinctly include among the purposes of the University the promotion of research and the advancement of science and learning. This is a matter which cannot be passed by in silence, because it is one of those questions about which difference of opinion exists even within the senate of the University itself. This is shown by what occurred at the presentation for degrees last May. Lord Rosebery was present on the platform and everybody was very glad to see him, but there is great danger in yielding, as the Vice-Chancellor quite naturally did, to the temptation to invite a distinguished visitor to say a few words on the spur of the moment, unless you are quite certain beforehand as to what he will say. For on being asked to speak, Lord Rosebery expressed the opinion that the University should teach and should have nothing to do with research, which proved to my mind that he had never thought seriously about the question. Nevertheless, this remark was received with evident approval by a considerable part of the audience, and was of course reported fully in all the newspapers.

There are two influences exercised by newspapers which seem to me distinctly mischievous. The one is the diffusion of the idea that mere novelty is a virtue, that things of yesterday are more interesting and important than the things of any day before; and the other is that the utterances of a prominent public man, on any subject whatever, are better worth having than the opinion of the man who has given his whole life to it, and I venture to say that public men are not always cautious enough in what they say on subjects to which they have given no attention, considering the weight attached by the public to all their words.

But as to this question of research in all places of higher instruction, what *a priori* judgment can compare with experience already gained? I am not one of those who willingly refer to Germany, for I am weary of the exaggerated nonsense often talked about German competition and English incompetence. But it is easy to see that the universities of Germany have settled the question for us and all the rest of the world by simply acting on the advice and example of Liebig, to whose influence much of her present prosperity is due.

Newman, as already stated, did not think that scientific or philosophical discovery should be the business of a university, but there is a splendid passage in his famous book, "The Idea of a University," which, though he does not refer to research, I cannot refrain from tearing away from its context, because it supplies such a vivid picture of the benefits which attend the existence of such a university in which the art of research is cultivated. He says: "This I conceive to be the advantage of a seat of universal learning, considered as a place of education. An assemblage of learned men, zealous for their own sciences, and rivals of each other are brought, by familiar intercourse and for the sake of intellectual peace, to adjust together the claims and relations of their respective subjects of investigation. They learn to respect, to consult, to aid each other. Thus is created a pure and clear atmosphere of thought, which the student also breathes, though in his own case he only pursues a few sciences out of the multitude. He profits by an intellectual tradition which is independent of particular teachers, which guides him in his choice of subjects and duly interprets for him those which he chooses. He apprehends the great outlines of knowledge, the principles on which it rests, the scale of its parts, its lights and its shades, its great points and its little, as he otherwise cannot apprehend them. Hence it is that his education is called 'liberal.' A habit of mind is formed which lasts through life, of which the attributes are freedom, equitableness, calmness, moderation and wisdom; or what I have ventured to call a philosophical habit. This, then, I would assign as the special fruit of the education furnished at a university, as contrasted with other places of teaching or modes of teaching. This is the main purpose of a university in its treatment of its students."

This I also humbly believe to be the *primary* purpose of university education, and this kept steadily in view all other things, the making of good doctors, chemists, engineers and merchants will be added thereto. This it is which, I think, will also best satisfy the want so eloquently put forward by Lord Rosebery last November, when, speaking not on the spur of the moment, but deliberately in the character of Lord Rector of the ancient University of Glasgow, he declared that "the first need of our country is a want of men. We want men for all sorts of high positions. We want men who will go anywhere at a moment's notice and do anything." And Lord Rosebery rightly thinks that it is the business of universities to produce such men. Of course it will be asked what has all this to do with the Royal College of Science, which is essentially a technical school for the training of teachers and of mining engineers and metallurgists. The answer is that we have accepted provisionally a place in the new university, and so the future working of the university cannot fail to have a deep interest for us. The nature of the entrance examinations which hereafter we shall be obliged to impose, the extent to which our courses of instruction and our college examinations are to be recognised by the university, the position of our associates in the university, are questions which remain to be considered and settled. And, further, I may add that the character and organisation of the teaching side of the university are subjects which will hereafter seriously influence our feelings towards it and the extent to which we shall be inclined to cast in our lot permanently with the new institution. A great opportunity now opens for the establishment of a seat of learning in the richest and most populous city in the world, richest not only in material wealth, but richest in collections of all that is precious to literature, science and art, richest in magnificent traditions and in memorials of the past. The question is, Will the people of London rise to the level of the great occasion? It concerns them more nearly than anyone else. Is London to fall behind a dozen provincial towns which by the exertions or the munificence of their own citizens afford such splendid evidence of local patriotism? London is no longer one city, but has become lately a number of adjacent towns. As they cannot well have separate universities, cannot the new municipalities unite in the same spirit which animates the citizens of Edinburgh and Glasgow, Manchester, Birmingham, Leeds and Liverpool, and help to make a real university common to them all?

I cannot hope to exercise much influence on the progress of events, but "out of the fulness of the heart the mouth speaketh," and I trust the views which I have expressed will not prove to be discordant with those of our late colleague, the distinguished Principal of the University, to whom we all look with hope and confidence for help in the solution of the multitudinous and tangled problems which the University of London still presents.

At the conclusion of his address Prof. Tilden distributed the prizes to the successful students.

MATHEMATICS AND PHYSICS AT THE BRITISH ASSOCIATION.

ALTHOUGH the number of members present at Glasgow was much smaller than was expected, the attendance at the meetings of Section A was well maintained. The papers presented to the Section were unusually numerous, and endeavours had to be made to restrict each speaker to the twenty minutes allowed by the rules of the Section. These endeavours were not always successful, and several papers which came late in the programme had to be given in too condensed a form to be properly appreciated. This was the case, unfortunately, with the "Note on the Theory of the Michelson-Morley Experiment," communicated by Principal Hicks. Prof. Morley, who was present, did not feel justified in discussing the question without having further details from Dr. Hicks. It is to be hoped that the debate which arose after the meeting of the Section was over, will lead to a repetition of these important experiments in the light of the new theory.

As in former years, the discussions which took place in the Section, either impromptu or by arrangement, formed some of the most interesting items of the proceedings. That on the magnetic effects of electrical convection was opened by Dr. Crémieu with a description of his experiments, all of which gave negative results. Dr. H. A. Wilson pointed out several causes which might possibly account for these results, but subsequent speakers expressed doubts as to them being adequate. On the whole, as Lord Kelvin said, we must wait for a repetition of the experiments under the simplest possible conditions before we accept as final a conclusion against which there is so much indirect evidence, and which, if accepted, would necessitate the entire reconstruction of electromagnetic theory.

A paper by Dr. Guillaume introduced a discussion on the proposed new unit of pressure, the megadyne per square centimetre, which was received with favour by the Section. It is very nearly the pressure exerted by a column of mercury 75 cms. long, at 0° C., at sea level in latitude 45°, and differs therefore little from the atmospheric unit at present used. Dr. Guillaume does not propose to interfere with the thermometric scale, and it seemed to be the opinion of the Section that when any change in the scale is made it should be "rationalised," and for convenience have a degree more nearly equal in length to a Fahrenheit than to a Centigrade degree. The discussion opened by Dr. Glazebrook was to have been on glass used for all scientific purposes, but on account of the small time at his disposal he had to restrict his remarks to optical glass, and gave an account of the advances made by Abbé and Schott in the construction of glass having the optical properties necessary for producing achromatic objectives. During the discussion it was pointed out by Mr. Hinks that the durability of some of the new glasses left something to be desired, one of the lenses in use at Cambridge having become partially covered by a fungus the removal of which would necessitate the taking apart of the objective.

Several of the reports of committees contained matter of special interest. That of the Electrical Standards Committee included the results obtained by Mr. S. Skinner on the slight difference of the amounts of silver deposited by the same current from solutions of silver nitrate in water and in pyridine. The Seismological Committee finds that the wind accounts for certain frequent small movements of the seismograph trace whose source had hitherto escaped detection. The report of the Committee on Underground Temperature contained tables of observations of temperature made in Michigan and in Silesia, down to depths of about 2000 metres. It seems, however, of little value to publish such tables without information as to the nature of the strata met with at different depths. The report of the Committee on the Determination of Magnetic Force on board Ship consisted of Captain Creak's description of the modified dip circle he has devised for carrying out the determination by Lloyds' method. The tests of the instruments having proved them satisfactory, two have been sent out in the *Discovery*, and one in the German ship *Gauss*, for use in the Antarctic.

Of the ordinary communications, that by Lord Kelvin on the absolute amount of gravitational matter in any large volume of interstellar space probably attracted the largest audience. Lord Kelvin gave a *résumé* of the arguments he brought forward in the *Philosophical Magazine* for August, to show that if 25 million years ago 1000 million masses equal to that of our sun had been distributed through a sphere of radius 3×10^{16} kilometres they would have now acquired velocities about equal to those known to be possessed by the stars visible to us. It seems, therefore, probable that the total amount of gravitation matter of our universe does not differ greatly from that of 1000 million suns. The same line of argument may be carried out for the mass distributed as atoms initially throughout space, and we then have the nebular hypothesis reduced to atomic dynamics.

Prof. Gray gave an account of the work he is doing in conjunction with his pupils on the viscosities of liquids and solids and the effect on them of changes of temperature, magnetisation, &c. Some of the most interesting of the results obtained were communicated to the Royal Society in June, and the experiments seem likely to have an important bearing on molecular theory. Dr. J. T. Bottomley's paper on radiation of heat and light from a heated solid was taken at the end of a sitting and received scant attention considering the importance of the subject. Dr. Bottomley finds by measuring the power absorbed by electrically heated polished or blackened platinum wire and strips placed in vacuo, that at the same temperature the blackened radiates four or five times as much energy as the polished surface, and that when the luminous appearance of the two is the same their temperature is practically the same. Prof. Morley and Mr. Brush have been determining the influence of water vapour on the energy lost by a heated body placed in an enclosure containing air, hydrogen or water vapour. At low pressures water vapour transmits heat more rapidly than air, but not so rapidly as hydrogen. In this connection Prof. Morley has devised a new pressure gauge capable of measuring pressures down to about a ten-thousandth of a millimetre of mercury. It consists of a U-tube containing mercury, on one of the free surfaces of which the pressure to be measured acts. The depression produced is measured by the amount of tilt of the tube necessary to bring the two mercury surfaces back into contact with two platinum points in the tube. A complete account of the arrangement is to appear shortly in the *American Journal of Science*.

Prof. Callendar communicated the results of applying a small correction hitherto thought negligible to the values of the specific heat of water between 0° and 100° C., determined from the observations of Dr. Barnes with Callendar's apparatus. The high degree of accuracy which Mr. E. H. Griffiths has attained in measuring temperature by the platinum thermometer has enabled him to determine the depression of the freezing points of extremely dilute solutions, and as a result he can now state that the depression produced by dissolving one gram-molecule of potassium chloride in a thousand grams of water is, to about one part in two thousand, double that produced by the solution of one gram-molecule of sugar.

Mr. B. Hopkinson brought forward a new argument for the existence of an ether. Although at certain times the two stars of a spectroscopic binary are moving in opposite directions at right angles to the line of sight with great velocities, the doubling to be expected, if aberration is due to relative motion of source and receiver, has never been observed. Aberration must then be due to the motion of the receiver with respect to something not matter, and be unaffected by relative motion of this something and the source. This "something" is the ether. Dr. Johnstone Stoney was unable to attend the meeting, and his paper on the possibility of obtaining interference between light from different sources had to be taken as read. Dr. Stoney believes he has obtained undoubted experimental proof of the possibility, but the matter must be held over till his proof can be considered and discussed.

Prof. Schuster gave an account of his experiments on the passage of electricity through mercury vapour. They seem to indicate that pure mercury vapour is a non-conductor.

Prof. Minchin described the latest form of his photo-electric cell, which consists of two selenium coated aluminium wires dipping into certain solutions, and produces a measurable E.M.F. when one wire is exposed to the light of a star. An arrangement so sensitive should have a great future before it.

In the meteorological department of the Section, papers by Messrs. W. N. Shaw and R. W. Cohen, on the effects of sea temperature and wind direction on the seasonal variation of air temperature in these islands, were read. The presence of the sea delays each seasonal change of temperature, and the authors are investigating the effect of the direction and temperature of the prevailing winds on the air temperature at the four principal stations of the Meteorological Office. Mr. F. N. Denison has found that the depression of the earth's crust due to an area of high barometric pressure can be detected by a seismograph at great distances from the centre of the depression, the instrument being tilted towards the area of high and from that of low pressure. The approach of a barometric depression is therefore indicated by the seismograph long before the barometer shows any sign of it.

In the mathematical department, Prof. Mittag-Leffler communicated a paper on a criterion for recognising the irregular points of analytic functions, an important extension of the theory of convergent series of powers to convergent series of functions. Mr. R. W. H. T. Hudson extended the idea of Newton's diagrams to the theory of differential equations. Prof. G. H. Darwin communicated a paper on Poincaré's pear-shaped figure of equilibrium of a rotating liquid, and Col. Cunningham announced the discovery of certain high primes, mainly by the use of the numbers called by Euler "idoneal." Several new theorems dealing with idoneal numbers were announced by Col. Cunningham and the Rev. J. Cullen. Further papers dealt with modified proofs of propositions already known.

In the astronomical department, Prof. Turner in his opening address called attention to the need of cooperation in astronomical work, cooperation which should not sink the individuality of the observer, or substitute routine for an alert spirit of inquiry and investigation. Prof. G. Forbes brought forward several facts which seemed to support his contention that there is a planet beyond Neptune with a mass about equal to that of Jupiter. Father Cortie announced that he had found the faculæ on the sun's surface followed the same law of rotation as the spots, and Mr. Hinks showed that the objections which had been raised to the determinations of the solar parallax from photographs of Eros, on the ground that it was a moving object, were unfounded. At the close of the sitting, Prof. Turner announced that Prof. Pickering had succeeded in taking a photograph of the spectrum of a lightning flash, and that important information would be forthcoming when the photograph had been measured.

C. H. LEES.

ZOOLOGY AT THE BRITISH ASSOCIATION.

THURSDAY, September 12.—The president's address was taken later than usual in order to afford opportunity of attending some other sectional address. In the afternoon the reports of committees and a few papers were taken, as follows:—

(1) Dr. Hepburn and Dr. D. Waterston gave a paper on the pelvic cavity of the porpoise as a guide to the determination of the sacral region in Cetacea. The chevron bones distinguish the caudal vertebræ in cetaceans, but there is no easy method of distinguishing sacral from lumbar vertebræ. The authors find a true pelvic cavity in the porpoise which corresponds to five pre-caudal vertebræ, and they suggest that these five vertebræ are to be regarded as sacral in Cetacea. They find considerable variation in the position of this sacral region in the different Cetacea, which they consider to be due to differences in the numbers of dorsal and lumbar vertebræ present.

(2) Prof. R. J. Anderson, on the relationships of the premaxilla in the bears. The premaxilla differs in the level and breadth of its articulation with the frontal, just as the nasals reach higher up and further back in some bears than in others. Genera allied to the bears approach them in regard to the relation of the premaxilla to the frontal, so do *some* of the Canidæ, but to a less degree, whilst other forms of the latter family have a wide interval between the premaxillæ and frontals. It is not difficult to account for the enlarged premaxillæ of elephants, whales and rodents, or for the short stout forms in Suidæ, &c.; but the seals, while in some respects resembling the arctoids, differ much in their premaxillæ. The isolated centres met with in some animals in the frontal region (*e.g.*, *Gorilla*, *Ursus*, *Labistus*) are wormian. The separate bone found in connection with the ventral part of the premaxilla in monotremes is not found in other mammals.

(3) Reports of Committees:—"On bird migration in Great Britain and Ireland."—The committee expresses its most grateful admiration of Mr. Eagle Clarke's invaluable services. Mr. Eagle Clarke supplies detailed statements on the migrations of the skylark and of the swallow, those of the former being of an extremely complicated nature.

"Index Animalium."—During the last year the period 1758–1800 has been dealt with. Arrangements had been made with the Cambridge University Press to begin the work of printing this first part of the Index in May, 1901. The indexing of 1801–1900 now continues. The whole of the work, as usual, has been done by Mr. C. Davies Sherborn.

Zoology of the Sandwich Islands.—This eleventh report states that Mr. R. C. L. Perkins has been working during the last year almost solely on the island of Oahu. The present position of the work is discussed.

Coral Reefs of the Indian Regions.—Mr. J. Stanley Gardiner has sorted out the marine collections from the Maldive and Laccadive archipelagoes into groups for the specialists, and some of these groups have already been worked up. The collections seem very complete, and the committee asks for assistance in publishing.

Table at the Naples Zoological Station.—In addition to the usual statistical information the committee give reports from Dr. Reginald Buller on the fertilisation process in Echinoidea, and from Dr. Hamlyn-Harris on the statocysts of Cephalopoda.

Table at the Plymouth Marine Laboratory.—The occupation of the table during the year is reported on.

Natural History and Ethnography of the Malay Peninsula.—Mr. W. W. Skeat gives an account (to Sections D, H and K) of the Cambridge Exploring Expedition. An extensive collection of vertebrates was made, and the first two species of *Peripatus* found in the Malay peninsula were discovered. These latter have recently been described by Mr. R. Evans.

Plankton Investigation.—Mr. Garstang reports upon his periodic work in the English Channel.

On September 13 the following papers were taken:—

(1) Mr. J. Stanley Gardiner, on the coral islands of the Maldives.—The Maldive group to the south-west of Ceylon is made up of a large series of comparatively shallow banks, separated from one another by channels of about 170 fathoms in depth. They extend north and south as a chain, double in the centre, for 550 miles. All are covered with coral reefs, arising to the surface. Some banks have on their circumferences the single ring-shaped reefs of perfect atolls, while others are studded with numbers of small isolated reefs, many of which are of circular form with shallow lagoons (atollons). The two classes of bank merge into one another, and the changes, going on at the present day, are such that the atolls may be supposed to have arisen by the fusion of the smaller reefs. All land in the group owes its origin directly or indirectly to elevation, and in most atolls is very markedly washing away. Everything points to a state of rest at the present day. The atoll reefs are perfecting themselves on all sides, and passages are closing up. The reefs, however, are not broadening, but to a certain point narrow as they become more perfect. The central basins of atollons are everywhere coming into free communication with the lagoons of the atolls. There is no trace of the filling in of the latter; indeed, such evidence as was found pointed, on the contrary, to their further widening and deepening and to the gradual destruction of the shoals and lands within the encircling reefs. The Maldive group marks the existence of an ancient land-area, but the changes going on are not consistent with the view that the reefs were formed on the subsidence of the land. The various reefs appear rather to have grown up separately on slight elevations of a common plateau at a depth of 150 fathoms,

while the plateau itself seems to have been formed by the washing away of the original land by wave and current actions.

(2) Mr. E. J. Bles, on a method for recording local faunas. Mr. Bles urges the use of uniform slips as in a library card catalogue, each slip to contain name of species, locality, date of capture, &c. The advantages of cooperation should be combined with this coordination of the recorders.

(3) Prof. J. Arthur Thomson's germinal selection in relation to inheritance was an attempt to test the utility of Weismann's subtle theory as a provisional interpretation of some of the important facts of inheritance. After inserting "a struggle of gametes and potential gametes" between the "histonal" or intra-organismal selection of Roux and the "germinal selection" of Weismann, he sought to extend Weismann's conception, pointing out that within the germ there might be three forms of struggle: (*a*) between determinants of the same character; (*b*) between determinants of quite different kinds; and (*c*) between the determinants and their somatic or more external environment. But the bulk of the paper was devoted to testing the theory as a unifying interpretation of otherwise unrelated facts of inheritance.

(4) Prof. Thomson also gave some notes on the behaviour of young gulls artificially and naturally hatched. After describing the actions of the young *Larus ridibundus* in the first three days after hatching, he noted that the young birds never ate deleterious or useless substances; that it took them a relatively long time to learn to recognise water in a shallow dish, though they drank with avidity when plunged into water or when they got their bills wet by pecking at their feet or at particles while standing in the water; that swimming and preening movements were seen in great perfection as early as the third day; and that the "kin-instinct" seemed very strong.

In the afternoon there were two papers by Mr. W. S. Bruce, on the fishes of the Coats' Arctic Expedition and preliminary notice of the fauna of Franz Josef Land, a paper by Dr. T. H. Bryce on heterotypical division in the maturation of the sexual cells, and a demonstration by Prof. Marcus Hartog and Mr. Nevil Maskelyne on the mechanism of the frog's tongue, showing the method of protrusion by means of a model.

On Saturday, September 14, the Section did not meet, but a number of the biologists took part in a very pleasant and successful expedition in connection with the Millport Marine Station. The party, on board the steamer *Ivanhoe*, accompanied the steam-yacht *Mermaid*, belonging to the station, on a dredging and trawling excursion round the shores of Cumbræ. In the afternoon the party landed and inspected the Marine Station, including aquaria, laboratory and the "Robertson" Museum. Copies of a special handbook issued by the Marine Biological Association of the West of Scotland, and compiled by the hon. sec., Mr. J. A. Todd, were supplied to the visitors. This gives an interesting account of the history of the Marine Station, and of the successive benefactions—Sir John Murray's "Ark," the "David Robertson" Museum, the present building, due largely to the liberality of Dr. Thomas Reid, the steam-yacht *Mermaid*, and other gifts from an anonymous donor—crowned, we believe, by an additional 3500*l*. given since this excursion to provide an extension of the building.

On September 16 the following papers were laid before the Section:—(1) Mr. J. J. Lister, on dimorphism in Foraminifera, with lantern illustrations. This subject was exemplified by the life-history of *Polystomella crispa*, in which two forms occur, the microspheric and the megalospheric, differing from one another in the size of the central chambers, the character of the nuclei and in relative frequency. The transition from the microspheric to the megalospheric form was traced by a series of photographs of an individual of the microspheric form, the protoplasm of which emerged from the shell and broke up into a brood of megalospheric young. These having reached maturity give rise in turn to actively motile zoospores. It was shown that the facts of the life-history are inconsistent with the view that the two forms represent the two sexes, but confirm that which regards them as alternating or recurring forms in a cycle of generations. While the megalospheric form arises asexually, there are considerable grounds for supposing that the microspheric form is produced by the conjugation of zoospores.

(2) Dr. J. Y. Simpson, on the relation of binary fission and conjugation to variation. The species specially examined were *Paramecium caudatum* and *Stylonichia pustulata*, and examination was restricted to (*a*) general outline, (*b*) total length, (*c*) extreme width, (*d*) distance between contractile vacuoles, (*e*) length of middle caudal bristle. In all five points variation was found. This was illustrated by microphotography. The author contends that there is variation in binary fission, and that the process is not merely one of duplication.

(3) Mr. W. E. Hoyle, on a new form of luminous organ, intrapallial, in Cephalopoda.

(4) Mr. R. Shelford, on the habits and life-histories of some Sarawak insects, illustrated by the lantern.

(5) Prof. J. C. Ewart gave a lantern demonstration on zebras and zebra hybrids. This was illustrated by an exhibition of three of the actual hybrids in the medical quadrangle (see description below).

(6) Dr. J. F. Gemmill, on a large nematode parasitic in the sea-urchin. This worm, which the author proposes to call *Echinonema grayi*, occurs in the perivisceral cavity, and seems to have escaped notice except for a brief mention by A. E. Shipley in 1900. The females are 60 to 150 cms. in length, and the males only 5 to 10 cms. An account of the anatomy was given.

(7) Mr. F. H. Marshall gave exhibitions of abnormal specimens of *Nephrops*, and of microscopic preparations of mammalian hairs.

Some of the members of the Section took part on the Monday forenoon in a conference between Sections C, D and E on the subject of limnology, with special relation to the scientific study of the lakes of the British Islands. It was announced that Sir John Murray and Mr. Lawrence Pullar had undertaken to defray the expenses of a survey to be undertaken by three scientific men during five years, and the conference discussed the best methods of carrying out the proposed scheme from the points of view of the different sciences involved.

On September 17, four papers were taken in the morning:—

(1) Mr. C. Forster Cooper, on the fauna of an atoll, with lantern illustrations.

(2) Mr. L. A. Borradaile, on the land crustaceans of a coral island. The author pointed out the importance of land crustaceans in the economy of tropical nature in general, and of a coral island in particular. He then enumerated the species he had observed in the island of Minikoi in the Indian Ocean with an account of their appearance and habits. Special emphasis was laid on the interesting land hermit-crabs of the genus *Coenobita*.

(3) Mr. J. S. Budgett, on the youngest known larva of *Polypterus*, with lantern illustrations. From his observations on the structure of the pectoral fin, the primordial cranium and the visceral arches of this larva, obtained in the Gambia in 1900, the author believed that the Crossopterygii showed affinities with the Selachii, but that the structure and development of the urinogenital organs, though in both probably of a very primitive nature, disclosed teleostean affinities, while the structure of the osseous skeleton has in many points been shown to resemble that of the Stegocephali and Amphibians. He therefore concluded that the Crossopterygii were a central group retaining relations with most of the great groups of Ichthyopsida, but not being actually ancestral to any one of them.

(4) Mr. J. Graham Kerr, on the origin of the vertebrate limbs. The author gave a short account of his hypothesis of the homodynamy of the vertebrate paired limbs with the true external gills. After pointing out the absence of solid foundation in fact for the two most widely accepted hypotheses of the origin of the paired fins, and having criticised these two views generally, he accentuated the probability that the two main types of limb, Ichthyopterygium (including Archipterygium) and Cheiropterygium, were derived independently from a simple styliform projection of the body (Stylopterygium), which was used, not for swimming, but for clambering about a solid substratum. This, from the evidence of Braus and others, was probably somewhere about the hind end of the branchial region. Now were there any projections from the body in this region from which the motor stylopterygium could have become evolved? Mr. Kerr pointed out that in the true external gills there existed a series of organs, projecting in various groups of lower vertebrates from the visceral arches (I.–VI. inclusive). These organs were potentially motor organs, as was shown by their powerful muscular apparatus and by the active flicking movements which they could perform; they were also potentially supporting structures, as was shown by the so-called "balancers," in which form the mandibular pair persisted in many Urodeles. He held that by far the simplest view of the origin of the paired limbs was that

they had developed out of a couple of the more posterior pairs of external gills, the girdles to which they were attached representing the skeleton of the corresponding branchial arches.

Mr. Kerr in the course of his paper controverted the view that the external gills were secondarily developed adaptive structures in the groups in which they occur; he also dealt with the difficulty that most true external gills contain no cartilaginous axis, pointing to the barbels of *Xenopus* with their cartilaginous axis, and to the rod of cartilage found by Budgett projecting into the base of the external gill of the hyoid arch of the young crossopterygian.

Tuesday afternoon's meeting of the Section opened with a lantern lecture by Major R. Ross on the story of malaria. He dealt in detail with the history of the various stages in the discovery and establishment of the mosquito theory, from the first fact, the discovery of the malarial pigment in 1849, to Manson's crucial experiment in 1900. He then passed to the prevention of malaria and other mosquito-borne diseases, and gave an account of the experiments now in progress in Sierra Leone and Lagos.

The session ended with three exhibitions—Dr. Francisco P. Moreno showing photographs of fossils in the La Plata Museum, Prof. Gilson a new sounding and ground-collecting apparatus, and Dr. J. Rankin a new orientating apparatus for the Cambridge microtome.

During the last few days of the meeting three of the zebra hybrids bred by Prof. Ewart were on view in the quadrangle (medical) adjoining the sectional meeting room. These hybrids were: (1) "Remus," the largest of the three, was born May, 1897, dam a 14-hands bay half-bred Irish pony. The mane of "Remus" was all but removed last April. (2) "Sir John," the small stout one, was born June, 1899. His dam is a yellow and white Iceland pony. "Sir John" probably reproduces fairly accurately the coloration of the primeval common ancestor of the horses and zebras. (3) "Birgus," the slender hybrid, was foaled May, 1900. His dam is a chestnut 14-hands polo pony. In 1898 this polo pony had twin hybrids, one of which goes extremely well and quietly in harness.

It is impossible to conclude even a brief account of the zoology of the meeting without at least a passing reference to the excellent volume on the natural history of Glasgow and the west of Scotland issued under the title "Fauna, Flora and Geology of the Clyde Area" as one of the three handbooks prepared by the local committee. A large number of specialists have collaborated in the production of the lists and articles, the result being a work of great completeness and of more than local interest, and of permanent value.

GEOGRAPHY AT THE BRITISH ASSOCIATION.

THE work of Section E at the meeting at Glasgow maintained the feature which has been noticeable for the last two or three years; the number of "popular" papers was comparatively small, while papers presenting the results of detailed research, or laying down foundations of future work, formed a distinct majority. Although the change has led to a marked diminution in the average numbers attending the meetings of the Section, it must be regarded as satisfactory, inasmuch as it indicates an increase in the annual output of scientific work by geographers in this country, and the fact is all the more gratifying in view of the difficulties in the way of geographical research, to which Dr. Mill drew attention in his presidential address. Dr. Mill laid his finger upon the true reason why "the few attempts which have been made in this country to promote the study of geography or to diminish the discouragements to geographical research have had but slight success" when he pointed out that "amongst the not inconsiderable number of teachers of geography in the universities and colleges of Great Britain there is not one man who receives a salary on which he can live in decent comfort so as to devote all his time, or a substantial part of it, to geographical research; and the same is true of every official of all the geographical societies." Until there are properly equipped centres offering adequate opportunities for research as well as teaching, we cannot expect students of geography to receive the intellectual stimulus which research alone can give, nor can we develop a system of geographical teaching suited to our special educational needs and methods, and capable of satisfactory extension to our schools.

Following the delivery of the president's address on Thursday morning, Mr. E. G. Ravenstein read a paper on Martin Behaim. Martin Behaim fills a place of some prominence in the history of geography on three grounds: firstly, the historian João de Barros, writing in 1539, states that he was a pupil of Regiomontanus, and was appointed a member of a committee which devised a method of "navigating by the sun"; secondly, Behaim claims to have commanded a vessel in Cão's second expedition; and thirdly, during a visit to Nürnberg in 1490–93, he superintended the manufacture of a terrestrial globe, which survives to this day. Mr. Ravenstein seriously doubts the first claim, rejects the second, and fully admits the third.

The tenth and final report of the Committee on the climate of Tropical Africa was also presented. In this report, drawn up by Mr. Ravenstein, abstracts of the meteorological observations received during the year are published, and a review is given of the work of the Committee since its first appointment in 1891. In completing its labours, the Committee recommends that where local provision is not made for the publication of observations, the registers should be forwarded in future (through the Foreign or Colonial Office) to the Meteorological Council or to the secretary of the Royal Meteorological Society. Copies of the "Hints to Observers," published by the Committee, may be obtained from the secretary of the Royal Meteorological Society.

Dr. A. J. Herbertson read a paper on the morphological divisions of Europe, in which he pointed out the inadequacy of the ordinary physical map for many of the purposes of the geographer. The paper was illustrated by a new "morphological" map of Europe, based primarily on the work of Suess, in which Europe was divided into physical regions, taking into account, not merely configuration, but composition and structure, and by a few well-chosen examples, such as the comparative structure of the south-east of England, the Seine basin, and the German Jura, Dr. Herbertson showed the undoubted value of maps of this type for purposes of both research and teaching.

The first paper in the afternoon was one by Mr. G. G. Chisholm, on geographical conditions affecting British trade. After illustrating his contention that geographical conditions, although often disregarded, were really important factors to be taken into account, by pointing out that Glasgow remained unimportant, both commercially and industrially, until the development of Transatlantic trade, Mr. Chisholm discussed the effects which improvements in means of communication, electric transmission of power, and other modern developments, are likely to produce in the trade of Great Britain as compared with that of other countries.

Prof. Alleyne Ireland read a paper on the influence of geographical environment on political evolution, in which he discussed the possibilities of native government within the tropics, concluding that while the natives of the tropics are not deficient in intellectual power, their "climatic discipline" renders them unfitted to play the part of legislators or responsible administrators, or to maintain a government sufficiently stable to admit of proper commercial development.

The Rev. Thomas Lewis gave an account of journeys in Portuguese Congo, in the course of which he has collected much valuable topographical information.

Friday morning was devoted to the geography of Scotland, and the proceedings afforded gratifying evidence that in spite of difficulties Scottish geographers are prosecuting research along various lines with vigour and success.

The first paper was one by Prof. G. F. Scott Elliot, on the effects of vegetation in the Valley and Plain of the Clyde. The general characters of the Clyde Valley in seven separate divisions were described—the sub-alpine, heather and peat, sheep pasture and arable districts; the Falls of Clyde canyon, the valley below the falls, and the flat and alluvial plains—and the successive stages in the formation of the valley slope were traced in a number of instances. It was shown that a perfect series of transitions can be found from the vertical scaur cut by the river to the continuous steep slope characteristic of the neighbourhood, and that the formation of the slope, in its various stages, was controlled by the vegetation.

Miss Marion Newbigin gave an account of a scheme which has been undertaken by the Scottish Natural History Society at the suggestion of Sir John Murray. It is proposed, firstly, to arrange, in a readily available form, references to papers already published on the natural history of the Forth Valley, including its botany, zoology and geology; and, secondly, the Society proposes to utilise its various sections and the labours of its individual members in the acquisition of a mass of detail in regard to the existing organic conditions in the valley of the Forth.

Prof. W. G. Smith described the methods and objects of the botanical survey of Scotland inaugurated by his brother, the late Mr. Robert Smith. The difficulties of grouping the flora comprehensively into "plant associations" having been got over, and the proper cartographic methods elaborated by a number of experimental surveys, it remains to carry out the work on the large scale. Great interest was taken in Prof. Smith's paper, and in the course of the discussion which followed Major Craigie gave the satisfactory assurance that when the survey is put on a definite basis it will receive assistance from the Board of Agriculture in the way of supplying details.

In the afternoon Dr. Francisco Moreno read an important communication on the anthropogeography of Argentina, in which he summed up the existing evidence as to the origin and distribution of different races of mankind in South America, and stated a number of problems awaiting further investigation. Mr. Hesketh Prichard gave an account of his journey in Patagonia, undertaken recently for the *Daily Express*. At the close of the meeting, Mr. Reclus-Guyou exhibited a specimen of the maps on natural curvature prepared by M. Elisee Reclus. These maps are drawn on a sheet of aluminium stamped to the curvature of a globe whose radius has the proportion to that of the Earth of the natural scale of the map.

On Monday morning Captain Lemaire gave an account of the Belgian expedition to Ka-Tanga under his command. The first part of Captain Lemaire's paper described the scientific results of the expedition, amongst the most important being an exhaustive investigation of barometric methods of determining altitudes in low latitudes; the second part consisted of an exhibition of part of the excellent collection of photographs made by the expedition. The expedition mapped more than 6600 kilometres of itinerary on a large scale, and one of the most remarkable features of the expedition was that "they left behind them no cause for complaint, or any ground for ill-will, among the native populations." Captain Lemaire's work was very appropriately described as a model and a guide for all modern explorers in Central Africa. In connection with this paper an exhibition of water-colour sketches by M. Dardennes, artist to the expedition, was held in the gallery of the Glasgow School of Art.

Dr. Vaughan Cornish presented the first report of the Committee on terrestrial surface waves, which dealt chiefly with observations of snow waves and ripples, and snow drifts and snow caps, made by Dr. Cornish during last winter in Canada. Considerable difficulties were met with in obtaining satisfactory photographs of the details of snow surfaces, but Dr. Cornish's admirable slides showed that these have been successfully surmounted.

Mr. H. N. Dickson read a paper on the mean temperature of the atmosphere and the causes of glacial periods, in which he drew attention to the fact that any change which may have occurred in the mean temperature of the atmosphere was probably accompanied by change in the temperature gradient between equatorial and polar regions, and therefore by modifications of the atmospheric circulation. It was suggested that this had not been sufficiently taken into account in discussing glacial and other phenomena connected with secular changes of climate, and that by taking it into consideration a comparatively small gain or loss of heat would suffice to produce the changes of temperature deduced from the geological record, while the changes in circulation at the earth's surface would account for many peculiar features of distribution.

On Monday morning a joint meeting was held with Sections C (geology) and D (zoology), to discuss the objects and methods of the scientific study of the lakes of the British Islands with special reference to the scheme of survey about to be carried out by Sir John Murray and Mr. Lawrence Pullar. Dr. Mill, who presided, read the following letter from Sir John Murray explaining the scope of the proposed survey, and stated that it had been undertaken as a memorial to the late Mr. F. P. Pullar:—

"I am sorry it is not possible for me to be present at the meeting of the British Association this year. I am very pleased to learn that a discussion has been arranged with reference to the proposed bathymetrical, physical, and biological survey of the fresh-water lakes of the United Kingdom. I have not, as yet, definitely settled anything with regard to the undertaking, but my idea is to endeavour to obtain the cooperation of three young university men who would take a real interest in the investigation and be likely to make something out of the researches in the way of experience and reputation; one to be a physicist, one a zoologist, and one a botanist. I propose to offer for the first year a salary of 100*l.* and expenses while actually engaged in field work at a rate a little better than is given to members of the Geological Survey. The principal work will be to sound the lakes and prepare the bathymetrical charts. While this is going on observations will be made concerning the temperature of the water at different depths and different seasons of the year, as well as how the distribution of temperature in the lakes is affected by wind and other conditions. Observations will also be made on the distribution of plants and animals in the different lakes at various depths and seasons, and on the deposits at the bottom of the lakes. The geological structure of the district in which the lakes are situated, the rainfall, and other allied phenomena will likewise receive attention. I would expect those who take part in the work at a salary to give their whole time to these investigations, and to work under my direction, but they will receive full credit for their work, and will be allowed to publish results in their own names. It may be possible to receive assistance from others who cannot give their whole time to the researches, and also to make collections and observations for those who are engaged in the study of special branches of limnology. It is probable that I will arrange to publish separately the results obtained in each catchment as soon as the survey of each basin has been completed, and then to publish a general account of the fresh-water lakes of the United Kingdom when the practical work of the survey has been finished. I propose to commence the organisation of the undertaking soon after my return to Scotland, and I hope to complete the whole work in five or six years."

A full debate followed, in which both geologists and biologists took part. Mr. John Horne intimated that the Geological Survey would, given the formal approval of the Board of Education, place any information in their possession at the disposal of Sir John Murray and his colleagues, and Colonel D. A. Johnston, of the Ordnance Survey, expressed his warm interest in the undertaking. A formal resolution expressing the great gratification of the meeting at the decision to carry on the work under the direction of Sir John Murray, and its sense of the munificence of Mr. Lawrence Pullar, was moved by Mr. Horne, seconded by Mr. Peach, and carried unanimously.

The proceedings on Monday afternoon opened with the report of a Committee—consisting of Sir T. H. Holdich, Colonel G. E. Church, Mr. E. G. Ravenstein and Mr. H. N. Dickson—which was appointed at the Bradford meeting to draw up a scheme for the survey of British protectorates, particularly in Africa. The Committee specially urges the importance of laying down a main triangulation so as to provide fixed points from which local surveys by explorers and others may begin, and of providing means of training native surveyors and topographers similar to those existing in India, such surveyors to be attached to exploring and similar expeditions as opportunities offer.

An important paper by Dr. R. Bell, of the Geological Survey of Canada, was next read by Mr. Mackinder. This paper dealt with the topography and resources of northern Ontario, or "New Ontario," and described the immense region lying north-west of the line of Lake Nipissing and the French River. The paper was accompanied by material for the construction of an adequate map of the district, which has not hitherto been represented with any detail.

Mr. A. Lawrence Rotch described some results of the exploration of the upper strata of the atmosphere by means of kites, and discussed specially the application of the method at sea. On land the wind is sometimes insufficient to raise the kites, but on board a steamship the artificial wind due to the motion of the vessel obviates this difficulty, and by altering the course relatively to the direction of the wind the action of the wind on the kite can be regulated to a very considerable extent. Successful experiments have been made at sea on board an Atlantic liner, and the value of extended investigations in the tropics, made from a ship which could be specially detailed for the purpose, can hardly be overestimated. The Association has appointed a strong Committee, with a money grant, to cooperate in these experiments.

The report of the Committee on changes of the land-level of the Phlegræan Fields, drawn up by Mr. Günther, was presented. Mr. Günther's work being still in progress, the report was of a preliminary nature, but it is satisfactory to note that the materials for the investigation have proved more valuable and abundant than was anticipated.

On Tuesday morning Mr. W. N. Shaw, F.R.S., exhibited a complete series of the weather maps published daily by various countries. Most of these bore the date January 1, 1901; others June 1, 1901. The list is interesting as showing the position of this branch of meteorology at the beginning of the twentieth century:—Austria, Bavaria, Belgium, British Isles, Denmark, France, Germany, Holland, Italy, Portugal, Russia, Saxony, Spain, Switzerland, Algeria, Australasia, Canada, India, Bay of Bengal, Japan, Mexico, United States, Roumania.

The rest of the morning was devoted to papers on the Antarctic expeditions. Dr. J. Scott Keltie described the organisation and equipment of the National Antarctic Expedition, and Dr. H. R. Mill gave an account of the voyage of the *Discovery* as far as Madeira, to which point he accompanied the vessel for the purpose of working out the details of the meteorological and oceanographical routine. Mr. W. S. Bruce then read a paper on the methods and plans of the Scottish National Antarctic Expedition, in which he announced that sufficient funds had been subscribed, entirely by Scotsmen, for one complete year's work in the Antarctic. It is proposed to purchase a whaler of about five hundred tons, and to leave this country in about a year's time. The ship will carry a scientific staff of five, five officers, and a crew of twenty. An attempt will be made to push as far south as possible in the Weddell Sea, and the deep reported by Ross in lat. 68° S., long. 13° W., will be specially investigated. The expedition will confine itself almost entirely to marine work, and it is not intended to winter in the ice.

In the afternoon Mr. H. Yule Oldham read a paper on the experimental demonstration of the curvature of the earth's surface. Mr. Yule Oldham has repeated Wallace's Bedford level experiment on the old Bedford River between Welney Bridge and Denver Bridge, a perfectly straight stretch of six miles. A mark was set up midway between the bridges, at the same height above water level as marks on the two bridges, and found to stand six feet above the line of sight. Records of the experiment have been obtained by the use of a special telephotographic lens.

Dr. R. Logan Jack then gave an account of an expedition in Western China, in which the Chengtu Plain was crossed five times, and a good deal of mapping done of the margins of the plain, and the courses of the rivers reaching it from the north. At the Maha gold mines the party received information of the massacres at Pekin, and were advised to make for Burma. Bhamo, in Upper Burma, was reached after many difficulties.

A paper, by Mr. Archibald Little, on the Crux of the Upper Yang-tse, was read by Mrs. Little. The paper contained an extremely graphic account of an ascent of the river during the flood season, and the condition of the country and of river navigation was compared with that obtaining during the winter.

The last paper was by M. Galeron, designer of the great celestial globe at the Paris Exhibition, on the representation of the heavens in the teaching of cosmography. After pointing out the difficulty experienced by the student in realising the apparent positions and motions of the heavenly bodies from a study of the ordinary celestial globe, in which the celestial sphere was represented as seen from the "outside," M. Galeron exhibited and described an apparatus in which a celestial globe is made of thin muslin, and sufficiently large for the head of the observer to be placed at the centre. The apparatus, which can be constructed very simply and cheaply, enables the chief phenomena to be demonstrated with great clearness.

It is noteworthy that the Artisan's Lecture this year, although geographical, was not an account of travel and exploration, but an exposition of the application of geographical principles. In his lecture on "The Movements of Men by Land and Sea," Mr. Mackinder showed how the progress of civilisation has been affected by the configuration of the Earth's surface, and pointed out the profound changes going on in political and social life under our eyes, as the result of the development of the great ocean lines of communication and of the transcontinental railways. The lecture was a perfect illustration of the aims and methods of the "new geography," and should do much to make those better understood and appreciated.

EDUCATIONAL SCIENCE AT THE BRITISH ASSOCIATION.

THOUGH the new Section of the British Association was only appointed for a year, the success of the meetings at Glasgow was of so decided a character that the Section will probably become a permanent part of the Association. It can scarcely be said at present that an educational science exists, but the statement of methods and results, and the discussion of the relationships between principles and practice, apart from all political considerations, should do something to organise the conclusions of people who have given serious attention to educational problems. The Section will exert the greatest influence in connection with scientific studies; and there is no reason why it should not lead to improvements in methods of teaching as valuable as those which have been produced by the scheme for a course of work in chemistry, drawn up by Dr. H. E. Armstrong for the British Association Committee on the methods of teaching chemistry. It is not too much to say that this scheme started a revolution which gathers strength every day. The system of science instruction by didactic methods still exists in places, but only because the machinery for carrying on the work on more rational principles has not been obtained. Wherever the object is education, the methods of research have been introduced, and it is recognised that real scientific knowledge can only be gained by individual experience.

Educational Experiment and Research.

Sir John Gorst accepted the principle of research in education in his address as president of the Section, and Dr. Armstrong emphasised it in an early paper. The power of research, the art of acquiring information for oneself, must, he pointed out, be cultivated in all because it is the power on which advance in life depends. The chief work of the Section will be to teach this doctrine, and impress it upon the teachers. A science of education must be shaped, and a national programme must be constructed in which research methods are encouraged and teachers are trained to have sympathy with them. The humanists must enter into an alliance with the naturalists, and the union should take place on equal terms. At present our educational system is entirely one-sided. The schools still at best suffer science; they do not love it and the old universities do not even regard it as a necessary element of culture.

Reform will be brought about by the development of workshop and laboratory methods. The experimental method of teaching is adapted to the curiosity and activity of the average boy, and should be the basis of instruction at the earliest stages. Prof. L. C. Miall gave strong support to the experimental method, which he described as the most complete embodiment of the methodised art of trying, of ignoring failures and improving successes, and perpetually going on until the goal was reached. This is the habit it is desired to set up and which will take an important place in future educational work. Sir Michael Foster emphasised the view that science is not learnt in the lecture room, but in the laboratory. The first aim should be to teach a boy to think, and this can be done by practical work properly arranged. It has been stated over and over again that pupils who have been prepared by the older learning take to science more readily when they are brought to it than those who have been trained from the very beginnings in science. This, Sir Michael said, was easy to understand, because teachers in the humanities have been trained to teach for generations, while men of science are only now beginning to learn how to teach.

Methods of teaching are of great importance, and the British Association can be the means of producing improvements in them. Prof. H. L. Withers, however, in a paper on the scope of educational science, expressed the opinion that before deciding how this or that subject should be taught it is desirable to formulate a theory of the curriculum, that is, to arrive at some conclusion as to the proportional value of subjects. Mr. P. A. Barnett also took this view, the main argument of his paper being that the criterion of success in education must be, not what people have been taught to do or to make, but what they are and how they bear themselves in all the relationships of life. But the educational value of a subject even considered from this point of view depends upon the scope of the subject and the methods of teaching, so that a reasonable curriculum cannot be drawn up until a decision has been arrived at as to what is implied by the name of each subject.

As instances of differences of opinion as to what should be included in a subject and how the subject should be taught, the discussions on the teaching of elementary mathematics and of botany may be cited. In each case a whole morning was devoted to the expression of expert opinion and the statement of experience in relation to the subject under discussion. For the discussion of the former subject, a joint meeting was arranged with the mathematical department of Section A, and for the latter a joint meeting was held with the Section of Botany.

The Teaching of Mathematics.

In urging a reform of mathematical teaching, Prof. Perry remarked that he would teach mathematics—at all events advanced mathematics—in different ways to different students. In any case he thought the system of teaching boys elementary mathematics as if they were all going to be pure mathematicians must be altered. We taught all boys what is called mathematical philosophy that we might catch in our net the one demigod, the pure mathematician, and we did our best to ruin all the others. In his experience there was scarcely any man who might not become an advancer of knowledge, and the earlier the age at which you gave him the chances of exercising his individuality the better. Educate through the experience already possessed by a boy; look at things from his point of view—that is, lead him to educate himself. Through his whole mathematical course let him be taught through his own experiments, and do not call it waste of time to plot the stream lines, for example, after the algebraic academic answer of a problem has been arrived at. The unpractical nature of mathematical teaching, he held, caused men to leave common sense out of their teaching, and he instanced the great continental Polytechnics, where an elaborate course of many months, or a year, was often devoted to a subject, of which the general principles could be grasped in a practical course of a few weeks.

All advocates of orthodox methods seemed willing to sacrifice every form of usefulness of mathematics to the mind-training inherent in a perfect logical system—a huge complex deduced logically from simple fundamental truths. Where would be the harm in letting a boy accept the truth of many propositions of the first four books of Euclid, partly by faith, partly by trial; of giving him the whole fifth book by simple algebra; and in letting him assume the sixth book as axiomatic? He would allow him, in fact, to begin his severer studies where he was now in the habit of leaving off; and would let him put aside much more than is usually done, so that he would get quickly to the solution of partial differential equations and other useful parts of mathematics. He had been speaking of the training of the mathematician, and he might be wrong; but as to the educational training of the man who was to use his mathematics in the study of pure and applied physical science, he had no doubt whatever of the importance of skipping judiciously in all early mathematic work. In these days all men ought to study natural science, and in such study they required to have the knowledge of algebraic formulæ and the power to use them; to be familiar with the use of logarithms in computation; with the use of squared paper, and with the methods of the calculus. He held that dexterity in these is learned by quite young boys, and he felt sure that such dexterity could not hinder, and could only further, the mathematical study of the exceptionally clever student.

Mathematics was a powerful weapon to unlock the mysteries of Nature. If a man knew how to use the method, that would be enough; he could leave to others, who delight in that, the forging and complete study of the weapon. The average young engineer might be made to possess a power of using the methods of mathematics, which would be as easy to him as reading or writing or using any hand tool—a power which would never grow rusty, because it would be exercised every day of his life; and his present hatred of mathematics and theory of engineering was leading to disaster. Higher mathematics had become a very useful thing. As in the case of all other generally useful things, the complete study of its philosophy in the orthodox manner was not a necessary part of the school or college curriculum. In concluding his remarks, Prof. Perry defended himself against the charge which his engineering friends had brought against him, that he had an exaggerated notion of the importance to all men of possessing a love for mathematics.

The discussion upon the paper was commenced by Prof. Hudson. He said that a too common fault in teaching mathematics consisted in allowing the pupil to learn by heart propositions, formulæ and rules, instead of using them as a means of training the reasoning powers. He trusted that Prof. Perry did not really wish to recommend that method, but he was afraid that its advocates might quote Prof. Perry in their support. Elementary teaching should be so conducted as to prepare for more advanced teaching; nothing should have to be unlearnt. Geometry should be based on the observation and handling of models of solid figures, and thus could be begun at a much earlier age than was generally supposed. Prof. Forsyth criticised the vehemence of the attack which Prof. Perry had made upon the mathematician while sympathising to a considerable extent with his aims. He pointed out that subjects do not necessarily progress on the lines of direct usefulness, and that very many of the applications of the theories of pure mathematics had come many years—sometimes centuries—after the discoveries themselves; the weapon had lain ready to hand, but the man had not been there to use it. He also indicated briefly his views on the teaching of elementary mathematics, and advocated the inclusion of a course on practical geometry early in the pupil's career. With this suggestion, that the pupil should be led to pure geometry only after he had been accustomed to handle and to work with the figures with which geometry is concerned, all the subsequent speakers cordially agreed. Prof. Forsyth further desired to point out the need of a proper system of training teachers so that when they began their profession they would not have to devote their time to practising upon their earliest pupils the method that happened to suit their own particular temperament. Major MacMahon—the president of Section A—joined in the discussion, but confined his remarks to the subject of elementary teaching without entering upon the more important questions raised by the address, which he had already dealt with in his opening address to the Section. Prof. Rücker said that there seemed to be a general agreement among all the speakers that, in the case at all events of the younger children, the teacher ought to approach the subject as far as possible from the concrete side. He also held, with Prof. Perry, that a somewhat rapid advance was advisable in the first case, the various qualifications with which the general statements had to be guarded being entered upon later. While not attacking the system of examinations—which had come in for severe criticism by other speakers—he considered that it had its weak points, but that it was a necessary part of our educational apparatus. Prof. Silvanus Thompson and Prof. Henrici were in entire accord with Prof. Perry; and the latter expressed the hope that qualified mathematicians would prepare text-books upon the lines laid down in the address. Prof. Everett pointed out the need of distinguishing between technical and liberal education, and Prof. Miall criticised the system in which the needs of the pupil and teacher were sacrificed to the demands of the examiner and inspector. Mrs. W. N. Shaw spoke upon the bearing of the discussion on the education of girls; and there also joined in the debate, Mr. J. Parker Smith, M.P., Prof. Greenhill, Prof. Alfred Lodge, Prof. Minchin, Mr. E. M. Langley, and others.

An immediate result of Prof. Perry's address has been the appointment of an influential committee of the Association, with Prof. Forsyth as president and Prof. Perry as secretary, to report upon improvements that might be effected in the teaching of mathematics.

The Teaching of Botany.

The joint discussion on the teaching of botany was held in the rooms of Section K, Prof. Bayley Balfour being in the chair. Mr. Harold Wager introduced the discussion by reading a paper on the teaching of botany in schools. He said that more attention should be paid to methods of teaching if the subject was to take its proper place in the school curriculum as a part of the general scientific training. Too much time should not be spent in mere descriptive work; and the use of the compound microscope should not be encouraged. The right selection of topics was important. Such subjects as experimental plant physiology, the structure and germination of seeds, and the structure and function of the flower were specially to be commended. A good grip of fundamental principles and not an imperfect acquaintance with a vast number of facts was wanted in school teaching.

Prof. Bower read a paper on the teaching of botany in universities. He also urged that the use of the microscope in schools should not be allowed. It should be left to the university course. Thoroughness in special branches should be aimed at with advanced students, not encyclopædic knowledge. Method was far more important than mere information. Advanced students should be left to work independently as much as possible. Research should be encouraged, but futile investigations were a mistake. Stress should be laid upon writing up the results of any piece of work in good literary form.

In the subsequent discussion, Prof. Miall said that in his elementary teaching at the Yorkshire College the laboratory work was the most important part of the work. Lectures were not given, but after a period in the laboratory a discussion on the facts observed took place in the lecture room, and the students were expected themselves to give an account of their work. They very soon learnt to express themselves clearly and easily, and had little difficulty in passing examinations. Prof. Marshall Ward agreed that observations formed a very important part of elementary botany, and children could be taught to reason from facts observed. With advanced students research was a powerful stimulus in developing interest in the subject. Prof. Withers believed that the study of science might well begin with natural history. Chemistry and physics should then be taken, and such a subject as botany might again be taken up in the higher forms. But as a training in scientific method he thought the value of botany was often extremely small.

Prof. Armstrong considered that more attention might be given to systematic botany, and science altogether should be taken more seriously in schools, and at least half the school time should be given to practical work. Chemistry and physics, as well as botany, were required in order to give the student a good knowledge of scientific method. Dr. D. H. Scott said that there was often too much specialisation in the syllabuses drawn up for elementary classes. His experience as an examiner had shown him that the subject could be easily crammed without developing any real knowledge of the subject. Dr. Kimmins gave the opinion, as the result of his experience, that botany was often very badly taught in schools because of the want of properly trained teachers. He thought it was a pity that there was a tendency to replace it altogether by physics and chemistry.

Sir John Gorst said that it seemed to him that one of the best science subjects for purposes of general education was botany, especially for rural schools. The provision of laboratories and apparatus was a difficulty. Perhaps the County Councils might help with these. Properly trained teachers were required, and the subject should have attention in Training Colleges. Too many rural teachers at the present time were not properly qualified to give simple lessons in botany.

The chairman in closing the discussion said that it had been of great interest, and he felt that improvement would take place as soon as a good supply of properly trained teachers could be obtained.

Organisation and Administration.

The other subjects dealt with in the Section belong more to the organisation and administrative side of education than to the aims, scope and methods of science teaching, so a brief mention of them will be sufficient in these columns. Sir Henry Roscoe introduced the subject of the organisation of technical and secondary education, and in commenting upon it Sir Michael Foster said that whatever legislation was brought forward it was to be hoped that no distinction would be made between primary and secondary education. Sir Philip Magnus spoke in favour of the unification of educational effort by the creation of local authorities to be responsible for education in their areas. A paper by the Bishop of Hereford on the influence of the universities and examining bodies upon the work of schools contained a plea for the recognition of science and modern languages as substitutes for Greek in Responsions. It was pointed out that the existing requirement of Greek from every candidate desiring to enter the older universities, together with the accompanying exclusion of modern languages and science, practically dissociates the whole class of modern schools or modern departments in schools from direct university influence, and the effect is found to be specially unfortunate in the modern departments of the large secondary schools. The paper will be printed in full by the Association. Among other subjects discussed were commercial education, and the mechanism of education in Scotland. Dr. J. H. Gladstone also read his annual report on the teaching of science in elementary schools, hitherto presented to the chemistry section, but there were few other papers, the system adopted in the arrangement of the programme being to accept only one or two papers for each meeting, and these to be on definite topics requiring discussion. By this means attention was concentrated upon particular aspects of educational work instead of being directed this way and that by a variety of papers. The system has worked so successfully that it will probably be followed at future meetings of the Section.

FORTHCOMING BOOKS OF SCIENCE.

Mr. Félix Alcan (Paris) gives notice of:—"Les maladies de l'orientation et de l'équilibre," by Prof. J. Grasset; "Manuel d'Histologie pathologique," by Profs. V. Cornil and L. Ranvier, illustrated, tome second.

Among Mr. Edward Arnold's forthcoming books are:—"The Balancing of Engines," by Prof. W. E Dalby, illustrated; "A Handbook on Fermentation and the Fermentation Industries," by Charles G. Matthews, illustrated; "Human Embryology and Morphology," by Dr. A. Keith, illustrated; "A Text-Book of Zoology," by G. P. Mudge, illustrated.

Messrs. George Bell and Sons give notice of:—"Elementary Science," by D. E. Jones and Dr. D. S. Macnair; "Inorganic Chemistry," by Prof. James Walker, F.R.S.; "An Introduction to the Comparative Anatomy of Animals," by Dr. G. C. Bourne, vol. ii.:—*The Coelomata*; "Elementary Differential Calculus," by Prof. A. Lodge, with an introduction by Prof. Oliver J. Lodge, F.R.S.; "An Elementary Treatise on Cubic and Quartic Curves," by A. B. Basset, F.R.S.

Messrs. A. and C. Black promise:—"A Treatise on Elementary Statics" (for the use of schools and colleges), by W. J. Dobbs; "New Descriptive Geographies: Africa, Central and South America, North America," edited by Dr. A. J. Herbertson and F. D. Herbertson.

Messrs. Blackie and Son, Ltd., will issue:—"The World of Animal Life, an Introduction to the Wonders of the Animal World," illustrated.

In the list of the Cambridge University Press we notice:—"Fables and Folk Tales from an Eastern Forest," collected and translated by Walter Skeat, illustrated; "Mathematical and Physical Papers," by Sir G. G. Stokes, F.R.S., vol. iii.; "Scientific Papers," by Lord Rayleigh, F.R.S., vol. iii. It is expected that the work will be completed in four volumes. "The Electrical Properties of Gases," by Prof. J. J. Thomson, F.R.S.; "Electric Waves," being an Adams Prize Essay in the University of Cambridge, by H. M. Macdonald; "A Treatise on Determinants," by R. F. Scott. A new edition by G. B. Mathews, F.R.S.; "The Algebra of Invariants," by J. H. Grace and A. Young; "A Primer of Botany," by F. F. Blackman; "Zoological Results based on material from New Britain, New Guinea, Loyalty Islands and elsewhere, collected during the years 1895, 1896 and 1897," by Dr. Arthur Willey. The entire work will be completed with the publication of part vi., which will be issued during 1901, and will contain Dr. Willey's monograph on *Nautilus* and other articles, including an account of the Ascidians by Prof. W. A. Herdman, F.R.S. "Reports of the Anthropological Expedition to Torres Straits by the Members of the Expedition," edited by Prof. A. C. Haddon, F.R.S., vol. ii.:—*Physiology and Psychology*. It is expected that the work will be completed in five volumes. "Biometrika. A Journal for the Statistical Study of Biological Problems," part i.; "The Fauna and Geography of the Maldive and Laccadive Archipelagoes," being the account of the work carried on and of the collections made by an expedition during the years 1899 and 1900 under the leadership of J. Stanley Gardiner, part i. of vol. i.; "Index Nominum Animalium," compiled by C. Davies Sherborn under the supervision of a committee appointed by the British Association and with the support of the British Association, the Royal Society and the Zoological Society, vol. i. (1758–1800); "Fossil Plants," a manual for students of botany and geology, by A. C. Seward, F.R.S., vol. ii.; "Electricity and Magnetism," by Dr. R. T. Glazebrook, F.R.S., "Hegelian Cosmology," by J. McT. E. McTaggart; "Essays on Educational Subjects," by Prof. S. S. Laurie.

Messrs. Cassell and Co., Ltd., will publish:—"The Earth's Beginning," by Sir R. S. Ball, F.R.S., illustrated; and new editions of:—"Tumours, Innocent and Malignant, their Clinical Characters and Appropriate Treatment," by J. Bland Sutton, illustrated; "Surgical Applied Anatomy," by Sir Frederick Treves, K.C.V.O., assisted by Dr. Arthur Keith, illustrated.

Messrs. W. and R. Chambers, Ltd., announce:—"The Nineteenth Century Series," in which we notice "Medicine, Surgery and Hygiene in the Century," by Dr. E. H. Stafford; "Discoveries and Explorations of the Century," by Prof. Charles G. D. Roberts; "Inventions of the Century," by William H. Doolittle; "Progress of Education in the Century," by James Laughlin Hughes and Dr. Louis R. Klemm; "Progress of Science in the Century," by Prof. J. Arthur Thomson.

Among the forthcoming works of Messrs. Chapman and Hall, Ltd., we see:—"Steam Boiler Economy; a Treatise on the Theory and Practice of Fuel Economy in the Operation of Steam Boilers," by William Kent, illustrated; "Elevation and Stadia Tables, for obtaining Differences of Altitude for all Angles and Distances, Horizontal Distances in Stadia Work, &c., with all necessary Corrections, &c.," by Arthur P. Davis; "Specifications for Steel Bridges," by J. A. L. Waddell; "A Manual of Assaying; the Fire Assay of Gold, Silver and Lead, including Amalgamation and Chlorination Tests," by Prof. Alfred Stanley Miller, illustrated; "High Temperature Measurements," by Prof. H. Le Chatelier and O. Boudouard, translated by George K. Burgess, illustrated; "Mechanical Drawing," by Lieut. Commander F. W. Bartlett, illustrated; "Practical Workshop Mechanics," by Wallace Bently; "The Human Figure in Motion; an Electro-photographic Investigation of Consecutive Phases of Muscular Actions," by Eadward Muybridge, illustrated; "Intermediate Practical Physics; a Manual for the use of Intermediate and Preliminary Scientific Students," by John B. Wilkinson; and new editions of "Notes on Thermodynamics," by H. W. Spangler, part i.; "A Text-book of Mechanical Engineering," by Wilfrid J. Lineham, illustrated.

Messrs. J. and A. Churchill's list contains:—"A Manual on Anatomy," by the late Prof. Alfred W. Hughes, edited by Prof. Arthur Keith; "Clinical Essays and Lectures," by Howard Marsh; "Gynæcological Pathology," by Dr. Charles Hubert Roberts, illustrated; "The Bacteriological Examination of Water," by Major Horrocks; "Serum-Therapy," by Prof. R. T. Hewlett; "A Text-Book of Clinical Medicine," by Dr. T. D. Savill; "A Hand-Book of Nursing, Medical and Surgical," by Dr. Hadley; "Elementary Ophthalmic Optics, including Ophthalmoscopy and Retinoscopy," by J. Herbert Parsons; vol. 4 of Groves' and Thorpe's "Chemical Technology"; "Electric Lighting and Photometry," by W. J. Dibdin and G. E. Cooke; and new editions of:—"A Manual of the Practice of Medicine," by Dr. Frederick Taylor; "A Text-Book of Medicine," edited by Dr. Pye-Smith, vol. i.; "Chemistry, Inorganic and Organic," by Prof. John Millar Thomson and Arthur G. Bloxam; "A Short Manual for Monthly Nurses," by Dr. Cullingworth; "A Simple Method of Water Analysis," by Dr. John C. Thresh; "The Pharmacopœia of the Throat Hospital"; "Dissection Outlines for use with Morris's Treatise on Anatomy."

The Clarendon Press announces:—"Micro-Anatomy," by Gustav Mann.

Messrs. J. M. Dent and Co. announce:—"A Primer of Physiology," by Dr. Alex. Hill; "Northern Mythology," by Prof. Kaufmann; "Beautiful Birds," by Edmund Selous.

Messrs. Duckworth and Co. will publish:—A new edition in one volume of "The Country Month by Month," by J. A. Owen ("A Son of the Marshes") and Prof. G. S. Boulger, with Notes by the late Lord Lilford.

Mr. Gustav Fischer (Jena) announces:—"Abhandlungen, Geologische und Palæontologische," edited by E. Koken, band v. heft 1; "Geologie der Radstädter Tauern," by Prof. F. Frech, illustrated; "Zur Lehre von der Blutzirkulation in der Schädelhöhle des Menschen, namentlich unter dem Einfluss von Medikamenten," by Dr. Hans Berger; "Fauna Arctica," edited by Dr. Fritz Römer and Dr. Fritz Schaudinn, zweiter band, erste lieferung; "Die Dipsomanie," by Dr. Robert Gaupp; "Die Malaria," by Battista Grassi, zweite vermehrte auflage; "Handbuch der Geschichte der Medizin," edited by Prof. Max Neuburger and Julius Pagel, erste lieferung; "Das Agglutinationsphänomen," by Dr. Fritz Köhler; "Topographischer Atlas der medizinischen Diagnostik," by Prof. Ponfick, zweite lieferung; "Handbuch der Hygiene," edited by Dr. Th. Weyl, erster supplementband, erstes heft; "Bedeutung eines systematischen Studiums des Skleroms," by Dr. von Schrötter; "Lehrbuch der vergleichenden Entwickelungsgeschichte der wirbellosen Thiere," by Profs. E. Korschelt and K. Heider, allgemeiner teil; "Technische Mykologie," by Prof. F. Lafar, zweiter band, erste lieferung; "Normentafeln zur Entwickelungsgeschichte der Wirbeltiere," edited by Prof. Dr. F. Keibel, drittes heft, illustrated; "Tropenhygiene mit spezieller Berücksichtigung der Deutschen Kolonien," by Prof. F. Plehn; "Die Bakterien," by Drs. J. Schmidt and Weis, illustrated.

The announcements of Messrs. Charles Griffin and Co., Ltd., include:—"Trades' Waste, its Treatment and Utilisation, with Special Reference to the Prevention of Rivers' Pollution," by W. Naylor; "The Metallurgy of Steel," by F. W. Harbord, illustrated; "Elementary Coal-Mining, for the Use of Students, Miners, and others preparing for Examinations," by George L. Kerr, illustrated; "A Dictionary of Textile Fibres," by William I. Hannan, illustrated; "Sanitary Engineering, a Practical Manual of Town Drainage and Sewage and Refuse Disposal," by Francis Wood, illustrated; "Ferments and their Action, a Text-book on the Chemistry and Physics of Fermentative Changes," by Dr. Carl Oppenheimer, translated by C. Ainsworth Mitchell; "Tables and Data for the Use of Analysts, Chemical Manufacturers, and Scientific Chemists," by Prof. J. Castell-Evans, in 2 vols.; "A Text-Book of Physics," by Prof. J. H. Poynting, F.R.S., and J. J. Thomson, F.R.S., illustrated, introductory volume on *Properties of Matter*; "Diseases of the Organs of Respiration, an Epitome of the Etiology, Pathology, Diagnosis and Treatment of Diseases of the Lungs and Air Passages," by Dr. Samuel West, illustrated; "Official Year-Book of Scientific and Learned Societies of Great Britain and Ireland," eighteenth annual issue.

Mr. W. Heinemann's list includes:—"The Play of Man," by Prof. Karl Groos, translated with the author's cooperation by Elizabeth L. Baldwin; "The Regions of the World," a series of twelve volumes descriptive of the physical environment of the nations, edited by H. J. Mackinder:—"Britain and the British Seas," by the Editor; "The Near East," by D. G. Hogarth; "Western Europe and the Mediterranean," by Elisée Reclus; "Central Europe," by Dr. Joseph Bastoch; "Scandinavia and the Arctic Ocean," by Sir Clements R. Markham, F.R.S.; "The Russian Empire," by Prince Kropotkin; "Africa," by Dr. J. Scott Keltie; "India," by Colonel Sir Thomas Holdich; "The Far East," by Archibald Little; "North America," by Dr. Israel C. Russell; "South America," by Dr. John C. Branner; "Australasia and Antarctica," by Dr. H. O. Forbes.

Mr. H. K. Lewis's list is as follows:—"A Handbook of Bacteriological Diagnosis for Practitioners, including Instructions for the Clinical Examination of the Blood," by Prof. W. d'Este Emery, illustrated; "Transactions of the Dermatological Society of Great Britain and Ireland," vol. vii.; and new editions of:—"Elements of Practical Medicine," by Prof. A. H. Carter; "The Sanitary Inspector's Handbook," by Albert Taylor, illustrated; "Rough Notes on Remedies," by Dr. William Murray.

Messrs. Crosby Lockwood and Son announce:—"Prospecting for Gold," by D. J. Rankin, illustrated; "Mining Calculations, comprising Arithmetic, Algebra and Mensuration," by T. A. O'Donahue, illustrated; "The Pocket-book of Refrigeration and Ice-Making for 1902, with Diary," edited by A. J. Wallis-Tayler; "The Bacterial Purification of Sewage," by Dr. Sidney Barwise, illustrated; and new editions of "Water and its Purification, a Handbook for the Use of Local Authorities, Sanitary Officers, and others interested in Water Supply," by Dr. S. Rideal, illustrated; "Lockwood's Dictionary of Terms used in the Practice of Mechanical Engineering," edited by Joseph G. Horner; "The Health Officer's Pocket-book, a Guide to Sanitary Practice and Law," by Dr. Edward F. Willoughby, illustrated.

Messrs. Longmans and Co.'s list contains:—"The Great Deserts and Forests of North America," by Paul Fountain; "Human Personality and its Survival of Bodily Death," by Frederic W. H. Myers, 2 vols.; "Dreams and their Meanings," by Horace G. Hutchinson; "Intuitive Suggestion," by J. W. Thomas; "Higher Mathematics for Students of Chemistry and Physics, with Special Reference to Practical Work," by J. W. Mellor; "A Practical Guide to the Administration of Anæsthetics," by Dr. R. J. Probyn-Williams; "A Practical Treatise on Mine Surveying," by Arnold Lupton, illustrated; "Bricklaying and Brick-cutting," by H. W. Richards, illustrated; "The Mind of a Child," by Ennis Richmond.

Messrs. Sampson Low and Co., Ltd., promise:—"The

Nordrach Treatment for Consumptives in this Country," by James Arthur Gibson; and a new edition of "The Student's Chemistry," by R. L. Taylor.

Among the announcements of Messrs. Macmillan and Co., Ltd., we notice:—"The Sherbro and its Hinterland," by T. J. Alldridge, illustrated; "The Scientific Memoirs of Thomas Henry Huxley," edited by Sir M. Foster, K.C.B., F.R.S., and Prof. E. Ray Lankester, F.R.S., in 4 vols., vol. iv.; "Atlas of Practical Elementary Zootomy," being a revised edition of the zoological portion of the "Atlas of Practical Elementary Biology," by Prof. G. B. Howes, F.R.S., with a preface to the first edition by the late Prof. T. H. Huxley, P.C., F.R.S.; "The Scenery of England and the Causes to which it is due," by the Right Hon. Lord Avebury, F.R.S., illustrated; Macmillan's Manuals of Medicine and Surgery: "A Manual of Medicine," edited by Dr. W. H. Allchin, vol. iv. *Diseases of the Respiratory System and of the Circulatory System*, vol. v. *Diseases of the Digestive System and of the Kidneys*; "Assimilation and Digestion," by Sir T. Lauder Brunton, M.D., F.R.S.; "The Climates and Baths of Great Britain," being the Report of a Committee of the Royal Medical and Chirurgical Society of London, vol. ii. *The Midland Counties and Ireland*; "Outlines of Inorganic Chemistry," by Prof. W. Ostwald, translated by Dr. Alex. Findlay; "An Experimental Study of Gases," by Morris W. Travers, with a preface by Prof. William Ramsay, F.R.S.; "Lectures and Essays by the late William Kingdon Clifford, F.R.S.," edited by Leslie Stephen and Frederick Pollock, with an introduction by F. Pollock, third edition, in 2 vols.; "Philosophy, Its Scope and Method," a course of introductory lectures by the late Prof. Henry Sidgwick; "The Growth of Hegel's Logic," by J. B. Baillie; "Mind in Evolution," by L. T. Hobhouse; "Texts for a Course of Elementary Lectures on the History of Greek Philosophy," edited by Dr. Henry Jackson; "Mammals," by F. E. Beddard, F.R.S. (being vol. x. of the Cambridge Natural History); "Insect Life, Souvenirs of a Naturalist," by M. J. H. Fabre, translated from the French by the Author of "Mademoiselle Mori," with a preface by Dr. David Sharp, F.R.S., illustrated; "The Mystic Rose, a Study of Primitive Marriage," by A. E. Crawley; "An Elementary Treatise on the Calculus," by Prof. George A. Gibson; a new edition of "The History of Human Marriage," by Dr. Edward Westermarck, with preface by Dr. A. R. Wallace, F.R.S.; "Upland Game Birds," by Emerson Hough, illustrated; "Salmon, Trout," by Dean Sage and A. Nelson Cheney, illustrated; "The Deer Family," by the Hon. Theodore Roosevelt, T. S. Van Dyke, and H. G. Stone, illustrated; "Municipal Engineering and Sanitation," by M. N. Baker; "An Introduction to Celestial Mechanics," by Dr. Forest Ray Moulton; "Elementary Electricity and Magnetism," by Profs. D. C. Jackson and J. P. Jackson, illustrated; "A Primer of Calculus," by Arthur S. Hathaway, illustrated; "The Practical Methods of Organic Chemistry," by Prof. Ludwig Gattermann, a new edition of the authorised translation by Dr. William B. Shober, illustrated; "The Applications of the Kinetic Theory to Gases, Vapours, Pure Liquids, and Solutions," by Dr. William Pingry Boynton, illustrated; "The Protozoa," by Dr. Gary N. Calkins, illustrated; "The Röntgen Rays in Medicine and Surgery, as an Aid in Diagnosis and as a Therapeutic Agent," by Dr. Francis H. Williams, illustrated; "Cyclopædia of American Horticulture," edited by Prof. L. H. Bailey, illustrated, vol. iv., completing the set; "First Lessons in Agriculture," by Prof. L. H. Bailey; "University Text-book of Botany," by Prof. Douglas Houghton Campbell, illustrated; "The Principles of Stock Breeding, the Application of Biological Laws to the Breeding of Domestic Animals (including Poultry), whether for Fancy or Profit," by Prof. W. H. Brewer; "Dictionary of Philosophy and Psychology," edited by Prof. James Mark Baldwin, with an international body of collaborators, in 3 vols.; "A Student's History of Philosophy," by Prof. Arthur Kenyon Rogers; "An Introduction to Psychology," by Prof. Mary Whiton Calkins; "Mental Growth and Control," by Dr. Nathan Oppenheim; "The College Student and his Problems," by Dr. James H. Canfield; "The Child's First Book in Science," by Dr. Edward S. Holden, illustrated.

Messrs. Methuen and Co. will publish:—"Head-Hunters, Black, White and Brown," by Prof. A. C. Haddon, F.R.S., illustrated.

Mr. Murray's list includes:—"National Education, a Symposium," edited by Laurie Magnus; "Tubulous Boilers, based on a Short Course of Lectures delivered at University College, London," by Leslie S. Robertson, illustrated; "The Fixed Stars, an Exposition of that Branch of Astronomy which relates to them," by Prof. Newcomb; "Heredity," by Prof. J. Arthur Thomson, illustrated (Progressive Science Series); "The Dawn of Modern Geography, a History of Exploration and Geographical Science from the opening of the Tenth to the middle of the Thirteenth Century (A.D. 900–1250)," by C. Raymond Beazley, illustrated; "Dangerous Trades, the Historical, Social and Legal Aspects of Industrial Occupations as affecting Public Health," by a number of experts, edited by Dr. T. Oliver, illustrated; "The Natural History of Religion, based on the Gifford Lectures delivered in Aberdeen in 1889–90 and 1890–91," by Prof. Edward Burnett Tylor, F.R.S., illustrated; "The Soil," by A. D. Hall; "The Book of Ser Marco Polo, the Venetian, concerning the Kingdoms and Marvels of the East," translated and edited by the late Colonel Sir Henry Yule, revised throughout in the light of modern discoveries, with a memoir of Colonel Yule (compiled with the assistance of Miss Yule), by Prof. Henri Cordier, 2 vols., illustrated.

Messrs. George Newnes, Ltd., will publish in the Library of Useful Stories Series:—"The Story of Animal Life," by B. Lindsay, illustrated; "The Story of Euclid," by W. B. Frankland.

In the list of Messrs. Kegan Paul, Trench, Trübner and Co., Ltd., we observe:—"Assyrian Language, Easy Lessons in Cuneiform Inscriptions," by L. W. King; "The Book of the Dead, an English translation of the Theban Recension," with supplementary chapters, hymns, &c., and nearly 400 vignettes which do not appear in the larger edition published in 1897, by Dr. E. A. Wallis Budge; and a new edition of "Text-Book of Physiological and Pathological Chemistry," by G. Bunge, translated from the German edition by Florence Starling.

Messrs. G. P. Putnam's list includes:—"Zuni Folk-Tales," by F. H. Cushing, illustrated; "The Home Life of the Wild Birds," by F. H. Herrick, illustrated; and a new edition of "Thinking, Feeling, Doing," by E. W. Scripture, illustrated.

Mr. Grant Richards announces new editions of "Colin Clout's Calendar," by Grant Allen; and "Logic, Deductive and Inductive," by Carveth Read.

Messrs. Rivingtons announce:—"Chinese Turkestan, with Caravan and Rifle," by Percy W. Church; "Rivingtons' Junior Mathematics," by H. G. Willis, comprising Arithmetic, two parts; Algebra, two parts.

Messrs. F. E. Robinson and Co. will issue:—"Wild Sport in the Outer Hebrides," by C. V. A. Peel.

Mr. Walter Scott announces:—"History of Geology and Palæontology to the End of the Nineteenth Century," by Prof. Karl von Zittel, translated by Dr. M. M. Ogilvie-Gordon, illustrated; "The Study of Religion," by Prof. Morris Jastrow, jun.

Messrs. Seeley and Co., Ltd., promise:—A new and enlarged edition of "The Chemistry of Paints and Painting," by Prof. A. H. Church, F.R.S.

Messrs. Smith, Elder and Co. call attention to:—"Lectures on Chemical Pathology in its Relation to Practical Medicine, delivered at the University and Bellevue Medical School, New York City," by Prof. C. A. Herter.

Messrs. Sonnenschein and Co., Ltd., have in hand:—"Harlyn Bay and the Discovery of its Prehistoric Remains," by the Rev. R. A. Bullen; Heinze's "History of Contemporary Philosophy," translated by Prof. W. Hammond; Wundt's "Physiological Psychology," translated by Prof. E. B. Titchener; "The Student's Text-book of Zoology," by A. Sedgwick, F.R.S., vol. ii.; "Psychology, Normal and Morbid," by Dr. C. A. Mercier; and new editions of Hertwig's "Elements of Embryology," and Walters' "Sanatoria for Consumptives."

Mr. Fisher Unwin will issue:—"Alcoholism—a Study in Heredity," by Dr. G. Archdall Reid.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—A research studentship of 120*l.*, tenable for one year, has been awarded at Emmanuel College to Mr. G. L. Tuck.

THE new pathological laboratory at Oxford is to be opened by Sir William Church on Saturday next.

A NEW science building in connection with Colorado College, and which will cost 300,000 dollars, is in course of construction. Towards the amount required Dr. D. H. Pearsons has contributed 50,000 dollars, and an anonymous donor 100,000 dollars.

THE Calendar of the Royal Technical Institute, Salford, for the sixth session, 1901–2, has reached us, and contains full information respecting the various courses of instruction given at this well-equipped institution.

Science announces that the expenses of a department of anthropology in the University of California will be entirely borne by Mrs. P. Hearst. The department will pay especial attention to the study of the Indians of the Pacific coast.

AMONG recent professorial changes in American universities we notice the following:—Prof. E. M. Wood is to succeed Prof. H. Benner in the chair of mathematics and astronomy of Albion College, Mich., Prof. T. C. Esty will take the place of Prof. Baker as professor of mathematics in the University of Rochester, and Prof. P. Arnold will fill the chair of mathematics in the University of Southern California.

THE annual report of the Glasgow and West of Scotland Technical College has just been issued, and tells of much good work done and progress made during the period under review. The number of students has increased to the utmost capacity of the buildings, and the curriculum has been extended in several directions. After a close inquiry into the standard of instruction, the composition of its staff and the plan of its future operations, the Scotch Education Department and the Treasury have granted to the College a fixed annual subsidy on practically the same conditions as the annual grants to the English University Colleges. The authorities are much embarrassed by the poor class-room and laboratory accommodation, and it is to be hoped, therefore, that the sum required for the proposed building operations will be speedily forthcoming. So crowded is the College that the Governors have been obliged to announce that they are unable to consider any additional applications for admission to quite a number of evening classes.

THE *Alumni Weekly* of the University of Minnesota for September 23 contains an account of the new botanical station which has been built on Vancouver Island for students of botany in Minnesota and the north-west. The seaside station, as it exists, is but a beginning, and many things are required for its suitable equipment, such as a small steam-launch, a steam-pump, a system of water-pipes for fresh- and salt-water, an additional laboratory building and other conveniences; but the start made is an encouraging one. The party of students and others which visited the station during the recent season numbered twenty-nine, and a very successful gathering seems to have been held. The days were spent in studying the products of the shore and forest, and in the evenings brief botanical lectures were delivered by the teachers. The buildings are, it may be mentioned, at present planned to accommodate eighty workers.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, September 30.—M. Bouquet de la Grye in the chair.—The problem of the dissipation of heat in a thick wall with radiating surface, by M. J. Boussinesq.—Remarks on the formation of acids in plants, by MM. Berthelot and André. It has been found that there is no relation between the total amount of vegetable acids contained in a plant, in the free or combined state, and the amount of acid in the juice extracted from the various parts.—On the engraved and painted figures of the Palæolithic period found on the walls of the cave of La Mouthe (Dordogne), by M. Emile Riviere. A minute description of prehistoric drawings, the existence of which was first indicated in 1895. The cave is nearly filled up with débris of prehistoric man, who inhabited the cave at two distinct epochs, which are clearly distinguished by a stalagmitic layer which separates them. The drawings are of three kinds, simple line engravings, others filled with a brownish-red ochre, and a third a kind of striation of the rock. All, with one exception, represent animals, the most perfect being complete figures of a bison and of a kind of antelope. The wild goat and reindeer are also recognisable.—On differential equations of the second order with algebraical coefficients, by M. Paul J. Suchar.—On the variable state of currents, by M. A. Petot.—The calculation of the heat of volatilisation and heat of fusion of some elements, by M. de Forcrand. The relation $(L + S)/T = (l+s)/T = 30$ between the molecular weight M, the heat of fusion S, the heats of volatilisation and fusion L, l, and the temperature, is applied to the cases of phosphorus, arsenic and selenium.—Nitromannite and nitrocellulose, by MM. Leo Vignon and F. Gerin. It has been previously shown by one of the authors that the various nitro-derivatives of cellulose energetically reduce an alkaline copper solution. It is now shown that penta- and hexa-nitromannite behave similarly. This reducing power is not altogether due to the formation of mannose. Nitromannite, reduced by ferrous chloride, gives a mannite devoid of reducing power. From this point of view it behaves differently from the nitro-celluloses.—The formation of an isatin derivative of albumen, by M. Julius Gnezda. A substance giving the reactions of chlorisatin has been obtained from the products of the reaction between hypochlorous acid and peptone.—On the reproduction and development of *Peripatopsis Blainvillei*, by M. E. L. Bouvier.—On stolonisation in the hydroides, by M. Armand Billard.—The fibrovascular elements of the stem and frond of some Filicineacæ, by MM. C. Eg. Bertrand and F. Cornaille.—On the localisation and dissemination of antimony in the organism, by M. G. Pouchet. The toxic action of antimony and its localisation require doses of antimony much larger than with arsenic, the localisation of antimony being different from that of arsenic. The toxic action of arsenic is not diminished by the presence of antimony, but, on the contrary, appears to be somewhat increased.

CONTENTS.

THURSDAY, OCTOBER 17, 1901.

THE ENGINEERING LABORATORY.

Experimental Engineering. Vol. ii. Testing and Strength of Materials of Construction. By W. C. Popplewell, M.Sc. Pp. viii+404. (Manchester: Scientific Publishing Company, 1901.) Price 10*s.* 6*d.* net.

THERE is no doubt that the most striking feature in the increased provision of means for the scientific training of engineers during the last quarter of a century has been the great development of laboratories equipped for experiment and research in all branches of engineering. While as yet there is no general agreement as to the best avenue to the engineering profession, it is universally admitted that such a training as is possible in a well-arranged laboratory can be made a most valuable adjunct to any system of instruction or apprenticeship. This development alone has created a field for a series of text-books such as that of which the book before us is the second volume, while the fact that it is also intended to meet the needs of the large class regularly engaged in what is known as "commercial" testing serves to widen its scope, without in any way diminishing its value for more strictly educational purposes. The book contains a large amount of useful matter, collected with much discrimination from a great variety of sources, and we have little hesitation in saying that it will in very great measure meet the needs to which we have referred.

In his introduction, Mr. Popplewell explains that he has included a chapter on the mechanics of bodies under test loads, not with the view of instructing the novice in the fundamental parts of the subject, but simply in order to explain briefly the leading principles involved, and to record the formulæ to be afterwards used. Such brief explanations of general principles, however, are almost always unsatisfactory in themselves; it so often happens that in arriving at a simple formula the important matters are those which are omitted, so that the subject is presented to the student in a garb of spurious simplicity. Again, the student, allured by the brevity of such explanations, is strongly tempted to confine his investigation of the principles to the explanatory chapter and to overlook the author's disclaimer. The results of this tendency are only too apparent in the bald proofs so familiar to every examiner in the subject. And further, apart from its expressed limitations, Mr. Popplewell's chapter of theory is in itself in some respects open to criticism.

It is, for instance, important that the measure of a "strain" should be a number representing what may be called the strain-ratio, so that for any elastic deformation we have the simple relation

$$\text{strain} = \frac{\text{stress}}{\text{modulus}},$$

the modulus being the stress which would produce unit strain. We find, however, that while "strain" is correctly defined on p. 14, the very next page presents us with the unhappy equation

$$\frac{\text{stress applied}}{\text{modulus of elasticity}} = \frac{\text{amount of strain}}{\text{original length of the prism}}.$$

The discussion, again, of the relation between E and G, the moduli of elasticity and of rigidity respectively, is cumbersome and might be much simplified, and although it is pointed out that the result (that G is to E as 2 is to 5) depends on assuming that Poisson's ratio has the value 4, which is only partially justified by experiment, this result is quoted on p. 216 as having been deduced in the earlier chapter from purely theoretical considerations. Generally speaking there is a marked lack of elegance about Mr. Popplewell's mathematics; special instances of his cumbersome style may be found on p. 40, and again on p. 160.

On the other hand, he has done well to call special attention to the difference between the twisting moment in a bar in which, the state being entirely elastic, the stress is proportional to the radius, and that in a bar in which, the plastic state having been reached, the stress may be regarded as uniform over the section, a distinction which is sometimes lost sight of in reducing and comparing the results of observation.

The second chapter, a long one, is devoted to the description of testing machines, and the comparison of the advantages and disadvantages of the various types of large machines in general use will be found of great value not only by the works manager or teacher who may require a machine to suit special conditions, but also by the intelligent student, who is only too apt to regard the particular machine, on which it may be his lot to work, as embodying all the virtues, or it may be all the vices, of its kind. Many of the illustrations, particularly the diagrammatic views of different types of machines, are very good, and for a few more of these we could well spare the half-dozen or so of photographs, which have in most cases been taken in a bad light and have all suffered in reproduction. It is a pity to burden a text-book with general views which can be found, reproduced in much better style, in the makers' catalogues.

It were vain to attempt anything like an exhaustive description of the various measuring appliances now in use, as it seems to be a point of honour for each laboratory to design a special type, but Mr. Popplewell gives a short and sufficient account of the more familiar extensometers and gauges. More perhaps might have been said of optical methods of measurement, particularly of appliances depending on the principle of the optical lever, which is now largely used in many laboratories, or embodying a delicate spirit level, of which one instance only, Prof. Unwin's extensometer, is described.

Special chapters are devoted to descriptions of the methods of carrying out various tests in tension, compression, bending and torsion, and of recording and reducing the results, and these chapters are well done. In the account of bending tests we notice no reference to the bending of long rods of small section. Even if these tests are not of importance from the commercial point of view, they are of value in the laboratory from the simplicity of the apparatus and the ease with which the properties of different materials can be compared, and from the fact that elastic displacements large enough to be accurately measured with micrometer eyepieces can be used.

Several torsion machines are described, and the difficulty of obtaining a pure twisting couple is pointed out. It is the case, however, that in many of the torsional machines in ordinary use the method of measuring the torsional deformation is not sufficiently accurate to justify elaborate precautions against bending moments, although it is not difficult to devise quite simple apparatus for making these angular measurements. These simpler means are somewhat overlooked by Mr. Popplewell, but an excellent account is given of the more elaborate and accurate instrument designed by Mr. Coker.

We are glad to find that our author, while describing several of the standard forms of apparatus for taking autographic records, is alive to the fact that these records are of secondary importance so far as the determination of the properties of the material is concerned, although undoubtedly of great use in exhibiting the nature of these properties. In educational testing especially, as indeed in all laboratory work, there is a danger of fostering too great reliance on autographic records, and the supreme value of first-hand observations cannot be too strongly insisted on.

It must suffice here to mention that the sections of the book which deal with the tests of ropes, chains, struts and so on are sufficient for their purpose, that there is a useful account of cement testing, although perhaps enough weight is not allowed to the personal factor in mixing, and that tests of the other materials of building construction are also briefly dealt with. Some account is also given of the effect of varying conditions, such as temperature, annealing, and bending, on the properties of metals. The effect of repeated stress and of reversed stress is dealt with in Chapter xi., and it would add considerably to the practical value of this chapter if a description of some of the standard pieces of apparatus used in making these tests were included. The account of timber testing is somewhat brief, but the general course of such tests is described and some standard determinations are quoted.

In his final chapter Mr. Popplewell has collected and tabulated a large number of determinations of what he calls the strength properties of the various materials considered, and this chapter, which seems both comprehensive and up to date, will undoubtedly be much used for reference by all who have occasion to consider these properties. He also adds a bibliography of books and memoirs.

We find no reference to the microscopic investigation of the structure of metals, a subject which has so much advanced of late years. The subject, indeed, demands a volume to itself, and at present perhaps is more in the province of the metallurgist than in that of the engineer, but its application to the investigation of flaws in structural parts has already given it a practical bearing which ought not to be overlooked.

Throughout the whole volume the need of occasional calibration of any testing machine in ordinary use is not indicated, nor is any description of the methods usually adopted in carrying out such a calibration given. This is a matter of such importance from a practical point of view that we must attribute the omission to inadvertence, and it will no doubt be rectified in another edition. On the whole, notwithstanding the few omissions and defects to which we have thought it necessary to call attention, we heartily commend the book to all who have to do either with the commercial testing of materials or with the management of the testing departments of engineering laboratories.

A NEW SURVEYING INSTRUMENT.

Der Hammer-Fennel'sche Tachymeter-Theodolit und die Tachymeter-kippregel zur unmittelbaren Lattenablesung von Horizontaldistanz und Höhenunterschied. Von Dr. E. Hammer, Professor an der K. Technischen Hochschule in Stuttgart. Mit 16 Figuren im Text und 2 Lithographierten Tafeln. Pp. 52. (Stuttgart: Konrad Wittwer, 1901.)

PROF. HAMMER has long occupied himself with the problem of constructing an instrument which should give the surveyor the necessary data for plotting his work with the least possible difficulty. Indeed, his numerous references to his previous work, and to the criticisms he has from time to time offered on the work of others, make his introduction not a little difficult to read. But, since the history of his work connected with tacheometers is set out with true German completeness, it may be valuable to anyone who is working on similar lines. In 1893 the author began to solve the following problem: to devise a tacheometer-theodolite, by which at one operation and without reading an altitude circle the observer could determine both the horizontal distance and the difference of altitude of a selected spot from the instrument. This problem the author now claims to have satisfactorily solved, and the instrument is on the market; but notwithstanding this long preparation we gather that several small improvements touching the arrangement of the microscopes and the general mounting of the instrument are still contemplated.

The optical part of the instrument consists of a so-called Porro object-glass, in which two lenses are kept at a constant distance from each other. The principal object-glass has a focal length of 350 mm., and the second lens, placed at a distance of 340 mm., 220 mm., giving to the entire system a focal length of 335 mm. The focussing is effected by moving the object-glass, and the eyepiece views a diagram of peculiar construction on which the effectiveness of the instrument depends. No compass or altitude circle is furnished with the tacheometer, but these can be added if it is desired to use the instrument as a transit theodolite or for other purposes. Instead of an altitude circle, a prism is placed at the side of the telescope above the axis, in connection with which is a carefully constructed diagram, arranged to a scale, by which can be shown the amount of tilting given to the telescope. A second prism placed behind the ocular throws an image of the diagram into the field of view, and as the telescope is moved up or down the diagram is moved to the right or left of the field, thus causing the lines of the diagram indicating the amount of inclination to cut the vertical wire in the eyepiece at a different place. The diagram and mechanical adjustments are so arranged that by multiplying the observed displacement of the line from the zero by 20, the difference of altitude in metres will result, while another displacement multiplied by 100 gives the distance. Very great care seems to have been bestowed on the construction of the field diagram on which the accuracy of the instrument must much depend. The correctness of the coefficient could no doubt be effectually checked by the measurement of known distances and of differences of altitude. Some little inconvenience, it would seem, must arise from the fact that the zero of altitude does not correspond with the axis of collimation of the telescope. This displacement of the zero line has been necessitated by the desire to make the instrument available for the measurement of differences of altitude amounting to 30°, and to get the resulting displacement for such elevation it was necessary to use more than the semidiameter of the field. The author discusses the amount of error likely to arise from this cause and puts the result in a tabular form. Very full descriptions of the method of adjustment are given and some very practical remarks are made on the method of using the apparatus.

To judge by the examples that the author has given, the instrument should prove very useful in the hands of an expert. These examples show that in the measurement of a distance of 250 m. an error of about 0·6 m. may be apparent, while the average error in elevation over the same distance, and in which the variation of level amounts to about ± 7°, will amount to a few centimetres.

OUR BOOK SHELF.

Results of Meteorological Observations made at the Radcliffe Observatory, Oxford, in the eight years 1892–99. Edited by Arthur A. Rambaut, M.A. (Dubl. and Oxon.), Sc.D., F.R.S., Radcliffe Observer. Vol. xlviii. Pp. xxiv + 245. (Oxford: J. Parker, 1901.)

THE publication of a collection of meteorological observations made in 1892 may at first sight appear somewhat belated, and as giving promise of but little interest. But observations such as the greater part of those contained in this volume serve two purposes. There is first of all the immediate application of knowledge concerning the atmospheric variations whose usefulness is shown in weather prediction and similar purposes. Some may think that this is the main, if not the only, outcome of meteorological inquiry. But, apart from all ephemeral interests, the maintenance of a continuous record of the behaviour of the atmosphere is of great importance. The study of climatic oscillations throughout long periods is a study that is likely to be attended with great advantage and instruction. The long, costly and laborious series of observations, that are so carefully prosecuted at so many stations, can only be justified by their use in investigations which aim at the primary causes of atmospheric disturbance. The records of the Radcliffe Observatory hold a deservedly high place in such series, both for accuracy and for length of time during which they have been uninterruptedly pursued, and for the purposes of scientific meteorology the value of the present volume is undiminished by the length of time that separates us from the earlier observations. It will take its place among many worthy companions and hand on the history of the variation of climate to those who have the skill to read it.

A feature of great additional interest is given to the present volume by an inquiry into underground temperatures at various depths by means of platinum-resistance thermometers. This inquiry was originated under the direction of the late Mr. E. J. Stone, and has been vigorously prosecuted by the present director. The thermometers are placed at depths varying from six inches to ten feet; a greater depth, which was originally contemplated, being found impracticable owing to the presence of water in the soil. The present inquiry is limited, but precise. It concerns itself with the variation of temperature in dry gravel; and the thermal conductivity of a water-logged stratum, or of one greatly differing in constitution from that here investigated, does not come into consideration. The main conclusion to which the Radcliffe Observer is led in this investigation into the physics of the earth's crust is, that the annual variation of temperature is reduced to 0°·1 F. at a depth of 45·3 English feet, and to 0°·01 F. at 66 English feet. The semi-annual wave has the same limits at 21·4 and 36 feet, respectively. The temperature curves for the separate months of the year on which this result is based are shown graphically in a plate possessing many features of interest.

But of equal, if not of greater, importance is the inquiry into the accuracy of the thermometers themselves and their suitability for such investigations. One gathers that although very considerable difficulty was experienced at the outset, and not unnaturally with a novel kind of apparatus, these thermometers have stood the test with great satisfaction and proved themselves more trustworthy and more convenient than the long-stemmed spirit thermometers ordinarily employed in similar researches, and against which some obvious objections can be urged. The main difficulty in the use of the platinum-resistance thermometer seems to arise from a damp atmosphere affecting the connecting wires and impairing the insulation, but with sufficient precaution the recording apparatus is most sensitive and permanent.

The Telephone System of the British Post Office. By T. E. Herbert. Pp. xi + 218. (London: Whittaker and Co., 1901.) Price 3*s.* 6*d.*

MR. T. E. HERBERT describes the book before us as a practical handbook, and, from certain expressions used in the second chapter, he seems to be one of those practicians who have not overmuch sympathy with theoretical workers. It is not perhaps to be wondered at, therefore, if the preliminary chapters of his book, dealing with the fundamental principles of sound, electricity, magnetism, and telephony are handled in a very unsatisfactory manner. We are afraid that a reader, if he has not already acquired a thorough knowledge of the subject, will be liable to form erroneous impressions. Thus, to give one example, Mr. Herbert states that in an induction coil "the E.M.F.'s generated in the secondary coil are directly proportional to the current variations in the primary." Again, the description of the action of the Bell transmitter is, we are inclined to think, incorrect, as the same mistake is made here of not properly allowing for the time taken over a vibration of the diaphragm.

The greater part of the book is devoted to a detailed consideration of the apparatus and connections used by the Post Office. This would have been greatly improved if more care had been taken with the diagrams. It is a great pity that in a book of this kind, where clearness in the illustrations is so important, the lettering should be in some cases so small as to be unreadable. It is to be regretted, too, that such words as "nextly" and "inoxidible" are allowed places in the text. In spite of the defects, some of which we have tried to point out above, we have no doubt the book may prove useful to telephone engineers who are anxious to be helped over some of their practical difficulties, and are not particular about a clear understanding of the groundwork of their science.

Maps: their Uses and Construction. A Short Popular Treatise on the Advantages and Defects of Maps on Various Projections, followed by an Outline of the Principles involved in their Construction. By G. James Morrison, Memb. Inst.C.E., F.R.G.S. Pp. viii + 110. (London: Edward Stanford, 1901.) Price 5*s.* net.

A BOOK in English on map projections has long been needed, and the present work is a very welcome attempt to meet this need. It may be commended to all who have to deal with geographical questions, and to teachers of mathemathics and practical geometry who wish to find fresh exercises for their pupils.

The volume consists of an introduction, a popular account of eight common projections, followed by another chapter dealing with the same projections in a slightly more advanced manner, and concluding with a discussion of projections of small areas. The popular description is exceedingly lucid, and the style is everywhere clear. The main defects of the book are that it is not sufficiently systematic, its nomenclature is occasionally at fault, the practical constructions in some cases are not the simplest, and the drawing of the diagrams is somewhat careless, so that statements in the text cannot always be verified on the figures. For Lambert's equivalent azimuthal projection, the author says there is no special name, and he calls Lambert's equivalent cylindrical projection simply the cylindrical projection. He omits Bonne's projection and both the Sanson-Flamsteed and Mollweide (Babinet's), all of which should receive some notice even in a popular work.

He rightly insists on the value of gnomonic projections for seamen, and of equivalent projections in our atlases; and desires the production of cheap and simplified globes.

A. J. H.

Smokeless Powder, Nitro-cellulose and Theory of the Cellulose Molecule. By John B. Bernadou, Lieut. U.S.N. Pp. viii + 200. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1901.) Price dollars 2·50.

THIS small work is of an entirely different character to the usual text-books on explosives, the author confining himself mainly to a theoretical consideration of his subject. To all interested in the manufacture or use of modern explosives the book should be of interest, throwing as it does much light on the theory of nitro-cellulose and mixtures containing this body, such as cordite or powders containing metallic nitrates with nitro-cellulose.

The book is divided into two parts, there being four appendices occupying considerably over half the volume. This latter portion is of most interest, for the author has collected together translations of the admirable papers by (1) Vieille, "Researches on the Nitration of Cotton"; (2) Mendeléef, "Pyrocollodion Smokeless Powder"; (3) Bruley, "The Nitration of Cotton" (an extension of Vieille's work). Appendix iv. consists of an abstract of a lecture by the author on the development of smokeless powder.

In the early pages concise definitions and a list of synonyms are given for the various substances dealt with, which avoids much confusion.

Some interesting work is recorded on the behaviour of guncotton at low temperatures. With liquid air it was found to be "not only not an explosive, but practically a non-combustible; while non-nitrated cotton under similar conditions is a violent explosive."

The remarkable action of very low temperatures in effecting solution of nitro-celluloses is dealt with at some length. McNab and others have shown that an insoluble nitro-cellulose becomes soluble in ether-alcohol at $-50°$, and the author shows that these bodies are soluble in ethyl ether under the influence of intense cold, and with the exception of the highly nitrated insoluble variety, they are soluble in absolute alcohol under similar conditions.

Lieut. Bernadou, in the latter part of the book, advances an ingenious theory of progressive impulses in guns when firing nitro-cellulose-nitro-glycerin charges, or colloided nitro-cellulose with metallic nitrates incorporated. With cordite, for example, "conditions point to there being two intervals in the decomposition of the charge, during one of which a maximum quantity of nitro-glycerin, and, during another, a maximum quantity of nitro-cellulose is burning." Finally, there may be a third impulse due to combination of the gaseous products. This latter appears to obtain confirmation from McNab and Ristori's analyses of the products from the materials separately and cordite (*Proc.* Roy. Soc., lvi. p. 8.)

In the space of a short review it is impossible to deal in a satisfactory manner with the author's theory of the cellulose molecule, many points being open to debate. The author's formulæ show four OH groups in the unit molecule $C_6H_{10}O_5$, which necessitates the assumption that on nitration some of these groups are unattached, whereas if the molecule is considered as having only three OH groups the limit of nitration is easily accounted for. Again, we are asked to assume that at low temperatures ethyl alcohol "under strain" has the composition usually associated with methyl ether, and that colloidisation is brought about by half molecules of ether or alcohol (under strain!) combining with half molecules of the nitro-cellulose.

Catalogue of the Collection of Birds' Eggs in the British Museum (Natural History). Vol. i. By E. W. Oates. Pp. xxiii + 252. Illustrated. (London: Printed for the Trustees, 1901.)

WE have received from the Trustees a copy of this carefully compiled and beautifully illustrated volume, which reflects the greatest credit on all concerned in its production, and should prove invaluable to all ornithologists and egg-collectors. As a matter of fact, it is somewhat more than is indicated by its title, for the exquisitely coloured plates illustrate the chief types of egg form and coloration characteristic of the various groups of birds, so that it forms to a great extent a manual of "oology." We do not on the present occasion propose to review the volume in detail, reserving this till the work is completed. It may be mentioned, however, that the work is practically unique of its kind, the only other catalogue of eggs published by the Museum having been issued so far back as 1852, and treating only of British birds.

The Trustees have been well advised in securing the services of Mr. Oates, whose previous experience rendered him peculiarly qualified to undertake this important task. Of late years, owing largely to generous donors, the collection of eggs in the Museum has increased by "leaps and bounds," and is probably quite unrivalled elsewhere. At the present time it includes more than 50,000 specimens; but even this vast number, according to the author, represents only about one-third of the known species of birds. An interesting feature of the volume is the account of the growth of the collection, which forms a large part of the introduction.

With the bare statement that it includes the eggs of the ostrich-like birds, the tinamus, game-birds, hemipodes, sandgrouse, pigeons, rails, grebes, divers, penguins, petrels, auks, and gulls, we take leave, for the present, of a most valuable and instructive volume.

The Colours of Guillemots' Eggs.

YOUR reviewer, in dealing with Mr. R. J. Ussher's work on the birds of Ireland (see NATURE, November 29, 1900, pp. 101 and 102), had his attention particularly drawn to two statements concerning the eggs of the guillemot. In the first of these, which occurs on p. 364 of his book, Mr. Ussher puts forward the suggestion that "the beautiful varieties of colouring must help each bird to distinguish her egg from others lying near *until they all become stained and soiled*" (the italics are mine). This is certainly a very pretty hypothesis; but is not the earlier part contradicted by the part I have italicised? It is certainly indirectly contradicted by a statement on p. 365, where Mr. Ussher records his belief that when the eggs of the guillemot are found, as they sometimes are, in the nests of cormorants and kittiwakes, "the owners of the nest incubate the mixed clutches, and not the guillemots, for I have noticed (he writes) a kittiwake chase away one of the latter from its nest."

If this be so, may we not doubt the propriety of supposing that a probably not very intelligent bird like the guillemot has a better eye for varieties of egg coloration than the kittiwake or cormorant, which cannot distinguish the strange egg dropped in its nest? And if the guillemot has a keen eye for colour, and if this faculty be as useful to the bird as Mr. Ussher suggests, is it not remarkable that natural selection should have permitted the speedy obliteration by stains and soiling of such important guide-marks? Is it not also remarkable that the guillemot, which, on the above-stated theory, needs distinctive marks to guide her to her own egg, should so easily dispense with these marks when her egg is hatched and her young one, so like its fellow-chicks, stands before her?

Why, again, should each guillemot be provided with a conspicuous private egg-pattern when other sea-birds, her neighbours, have to find their homes without such aid?

We have no right to suppose that the guillemot needs guide-marks to enable her to perform acts which are simple in comparison with those performed by many other birds and mammals. The guillemot's egg is stationary. The young of the fur-seal wanders widely amongst thousands of its similar brethren, yet its mother, even after days of absence, never fails to recognise it and will be satisfied with no other. So, too, travellers in the Antarctic tell us that the penguins[1] of that region have no trouble in finding their own offspring. There is no need, however, to multiply instances of what is a perfectly well-known faculty in gregarious animals.

I cannot think that this theory of Mr. Ussher's, so easily made and proportionally difficult to disprove, accounts for the facts of the case.

On the whole, I am inclined to doubt if any *conscious* act of recognition be involved in the return of each guillemot to her own particular egg; for we know that many sea-birds, probably fearing the robberies of the larger gulls, do not willingly leave their eggs unprotected, so that in natural conditions a bird may never actually have to find its egg, but rather its mate whose turn of duty has expired. It seems to me, then, highly probable that, if any conscious act of recognition be involved, it must be dependent upon smell or some other kindred sense.

But surely it is simpler to regard the varied colours of the guillemot's eggs as due purely to a waste product of the bird's metabolism, a product which in some birds, of which the guillemot must be regarded as one, would be forthcoming in abundance at the exciting season of the year, when all the organs of the body are more or less upset by the reproductive processes?

If this view be adopted, diversity of colour follows almost as a matter of course. For it is natural to suppose that in a case like this, where eggs are laid side by side in such large numbers, the question of coloration is unimportant and any colour is admissible which is consistent with the chemical constitution of each particular bird. When I look at a series of eggs of the guillemot I am always reminded of a herd of domestic cattle or a flock of barn-door fowl. In these, when no artificial selection has restricted the colour, the variation is extremely abundant. Like that of the guillemot's egg, however, it has its limits, due to the possibilities of the chemical combinations in the animal concerned. So that while red guillemots' eggs are rare, blue and green cattle are unknown. Further, while in some cases, as in cattle and the eggs of the guillemot, the variation is rich, in others, as in the ass and the eggs of the hedgesparrow, for instance, the range of variation, for reasons at present unknown to us, but probably differing in each instance, is comparatively restricted.

In conclusion, I must add that I am in no sense an opponent of the prevailing theories of protective coloration in birds' eggs as a whole. Such protective colouring almost certainly exists, but I doubt if it be nearly as extensive as is generally supposed, and I would suggest that the coloration is in many cases purely physiological, an aspect of the question which has assuredly been too much nelected.

Orange River Colony. G. E. H. BARRETT-HAMILTON.

Addresses of Authors of Scientific Papers.

MAY I be allowed, through the medium of your columns, to point out the inconvenience that is caused by the omission of an address on authors' separate copies of scientific papers?

Several papers have reached me recently containing valuable and interesting results, but there is nothing to guide me in my search either for the authors' addresses or, in some cases, the name of the periodicals in which their papers were originally published. I am unable, therefore, to acknowledge the receipt of their gift, to send anything in exchange, or to enter into private correspondence with them on their results.

SYDNEY J. HICKSON.

The Owens College, Manchester, October 4.

The Recent Inverness Earthquake.

IN NATURE for September 26 it is stated that the recent Inverness earthquake was not felt in Edinburgh or Glasgow, and apparently the Milne seismograph at the Royal Observatory in the former city gave no indication of any movement. The shock, however, was distinctly felt in Paisley, a few miles west of Glasgow. There are in the Coats Observatory here two seismographs. One of these is a Milne, and it gave no record; but the other, which is Prof. Ewing's, marked the occurrence of the shock. The time as nearly as could be ascertained was 1h. 21m. 35s. The lateral movement was very slight.

ANDREW HENDERSON.

Paisley Philosophical Institution, Paisley, October 14.

THE VIRCHOW CELEBRATION.

A FEW days ago representatives of the world's science met in Berlin to do honour to one of the world's veteran men of science. The occasion of Prof. Virchow's eightieth birthday was seized by many learned societies and private individuals to express their appreciation of the great debt owed by mankind to this epoch-making thinker and worker. The Emperor of Germany bestowed upon him the great gold medal, and the King of Italy a picture in which the Professor's portrait was accompanied by that of his great Italian forerunner, Morgagni. The idea to frame these two scientific men together, whose work, although separated by two centuries of time, illuminated the same branch of knowledge, was certainly a graceful one.

Prof. Virchow was the son of a small farmer in Pomerania, and was born on October 13, 1821. He studied in Berlin, and his first appointment was in connection with the Charité, a hospital which has numbered among its staff many men of European fame. Shortly afterwards Virchow was appointed University Lecturer. About this time he fell somewhat into official disfavour on account, no doubt, of his sympathy with the revolutionary movements of 1848. He left Berlin for the quiet University town of Wurzburg. Here he attracted numerous students and workers, and formed a pathological school which, even after he had quitted it, continued to be one of the best in Europe.

The work by which Virchow will always be known is his "Cellular Pathology." As Lord Lister truly remarked, workers of the present generation cannot conceive the effect which was produced upon the medical world by this book. In 1826 botanists began to regard plants as collections of cells; in fact, Schwann firmly established the position of the cell as the unit of vegetable morphology. Owing, no doubt, to the less distinctly defined characters of the animal cell, it was not until later that Kölliker and others extended the cellular theory to animal tissues. Virchow, in 1858, found a wider application for this theory and demonstrated that pathological tissues also were collections of cells, and that the phenomena of their growth was covered by the generalisation *omnis cellula a cellula*. From that time till to-day Prof. Virchow has been an active worker in pathology, combining the highest critical faculty with an apparently perennial assiduity. In London he is well known; not many years ago (in 1892) he received the Copley medal of the Royal Society, and at that time his great achievements were referred to

[1] See Racovitza, "La vie des Animaux et des Plantes dans l'Antarctique," published by the Société royale belge de Géographie, p. 51, 1900.

at length by the late Sir James Paget in one of his most felicitous speeches. In 1898 he delivered at Charing Cross Hospital the Huxley Lecture, in the English language.

Prof. Virchow has from very early in his career devoted considerable attention to practical hygiene and anthropology. His work upon prehistoric cave-men and Swiss lake dwellings may be taken as a type of the thoroughness with which he accomplished anything he undertook. Last, but not least, the great pathologist was, and indeed is, a politician of no mean order. He entered the Chamber in 1862 and served there till 1878. His work as a politician was devoted to the cause of liberty and truth, and even those who did not agree with his doctrines were unanimous in their respect of his motives.

It is sincerely to be hoped that the aged Professor may for many years to come continue his valuable work, and to all students of science no item of the varied programme of the Virchow celebration was more welcome than the astonishing vigour and youthful earnestness with which the object of their congratulations for two hours, addressed them. F. W. T.

THE RECENT WORK AT STONEHENGE.

At a meeting held last March at Stonehenge and attended by representatives of the Society of Antiquaries, of the Society for the Protection of Ancient Monuments and the Wiltshire Archæological Society, various plans and measures were discussed and suggested for the better preservation of Stonehenge. The whole state of the surrounding neighbourhood being changed from its former quietude by the introduction of new elements, such as the military camps at Bulford, &c., the making of the new branch line of the South-Western Railway (from Grateley to Amesbury), it became necessary to meet the altered circumstances by the exercise of greater precautions for the care of the beautiful old Sun Temple standing in the midst of the grass-clothed downs —a thing of wonder and mystery to behold. The advice given to Sir Edmund Antrobus by the representatives of these societies was as follows, published in the *Times* of April 3.

Resolutions.

(1) That this Committee approves of the suggested protection of Stonehenge by a wire fence not less than 4 ft. high, following on two sides the existing roads and crossing on the west from the 331-foot level on the north road to the 332-foot level on the south road shown on the O.S. map (1–2, 500), Wilts sheet liv. 14.

(2) That the Committee recommends, without prejudice to any legal question, that the local authorities be requested to agree to divert the existing track-way or ridge-way from Netheravon now passing through the earth circle so as to pass from the 302-foot levels in the O.S. map immediately west of Stonehenge.

(3) That stones 6 and 7 with their lintel, and stone 56 (according to the numbering on Mr. Petrie's plan) be first examined, with a view of maintaining them in a position of safety.

(4) That, in the opinion of this Committee, stone 22 should be replaced, stone 21 be made safe, and the lintel of 21 and 22 be replaced in the most safe and conservative manner. The Committee also recommends the re-erection of stones 57 and 58, and their lintel 158.

(5) That the instructions to custodians already in force be approved with a few suggested alterations.

(6) That this Committee feels that it is impossible to overstate the value of the assistance which the County Council of Amesbury can give to the efforts made to preserve this unique monument.

(7) That these resolutions be sent to Sir Edmund Antrobus with the earnest thanks of the Committee, for the part he is proposing to take in the preservation of Stonehenge, also that it be left to him to communicate with the Press.

The fence was erected by Whitsuntide and is 1700 yards in circumference and composed of lightest barbed wire of a neutral tint and absolutely invisible at a distance, so that the traveller gets the whole effect of Stonehenge in its full grandeur instead of, as in former days, the view of the stones mingled with two or three flys, a cart, an old waggonette, and photographer's van, &c., to say nothing of picnic luncheons, spread out within the sacred circle. This fence encloses as large an area as possible,

Fig. 1.—The work at Stonehenge. Raising the leaning stone.

being well outside the vallum except on the west side, where a right of way interferes with the true circle. The next work undertaken—the most difficult and important of the whole—was the raising of the "leaning stone"—the largest monolith in England except Cleopatra's needle—to an upright position. This stone formed one of the uprights of the trilithon the fall of which was said to have been caused by the digging and researches of the Duke of Buckingham in 1620. The horizontal and the other upright (the latter broken in two pieces) now lie prostrate across the altar stone.

The great stone leaned considerably towards the N.E. and appeared to rest upon (actually touching at one point) a beautiful little pillar stone of syenite, the danger being that in some storm, especially after a heavy fall of snow and sudden thaw, the great stone would break in three pieces (having three veins) in falling, and also crush the smaller stone beneath it.

That a forward movement was continually taking place is shown by observations taken by Mr. Flinders Petrie some years ago. It then leaned at an angle of 62, which has been increased to one of 65 degrees lately. The work of the raising of the stone was begun on August 18 and finished September 25, and was under the direct supervision of Dr. Gowland, Mr. Detmar Blow, architect, and his assistant Mr. Stallybrass, and Mr. Carruthers, engineer. The first thing done was to make a fitting to the stone of a strong timber cradle so as to protect it from injury by the immense iron chains and ropes placed round it, these being attached to winches worked by men, so that the stone was actually "wound up," so to speak, into an upright position. Hydraulic jacks were also used. The whole thing was most carefully and slowly done, and devotedly watched over by workers. A rectangular excavation was made in front of the stone, a square excavation at the back. A frame of wood with numbers at equal distances apart was placed over the ground, which was excavated in sections, and the earth was most carefully sifted in layers through four grades of sieves in such a manner that the position of every object found could be recorded. The excavations round the base of the stone are now filled with concrete, and the large struts which uphold it will remain in their positions for six months, until the concrete be thoroughly set.

The objects found were one Roman coin at a shallow depth, and many chippings of both the blue and sarsen stones. Numerous flint axeheads and large stone hammers were also found at a depth of from two feet to three feet six inches underground; all tending to prove the great antiquity of Stonehenge—at least Neolithic. But all this will be discussed scientifically later on.

FLORENCE C. M. ANTROBUS.

BIRD LIFE IN THE CANARIES AND SOUTH AFRICA.[1]

ALTHOUGH the author can scarcely be congratulated on his choice of a title, which in our opinion is too prolix and disconnected, he has succeeded in producing a very readable and interesting little work, based on a stay of six months in the Canaries and a sojourn of about the same duration in South Africa. Much of the contents is devoted to the ordinary incidents of travel, but the special feature of the book is formed by the excellent series of photographs of birds in their native haunts. As every one who has tried bird-photography is aware, but little can be done with the camera in this respect except during the nesting season; but the author's object has been, not to obtain pictures of the birds while actually sitting, but in their natural attitudes when in the neighbourhood of their nesting places. In this way it is possible to show birds in positions which could not be attempted in a drawing; and the value of such pictures for the guidance of the taxidermist who desires to be true to nature cannot be over-estimated. Apart from getting near enough to the bird without disturbing it, there are, however, difficulties connected with this branch of photography which can only be fully realised by those who have had practical experience.

The ideal way of showing a bird, as the author tells us, is perhaps to portray it amid its natural surroundings, but, with rare exceptions, this is unfortunately a practical impossibility in photography. The chief difficulty with which the photographer has to contend is the background—whether this should be in proper focus at the expense of the bird, or *vice versâ*. In most of the photographs the background has been sacrificed; the birds standing out against a dark background, due to out-of-focus distance behind them. This method has the advantage of bringing into relief the various markings and details of the plumage in a manner that would otherwise be impracticable; and, at any rate from the naturalist's point of view, the author is to be congratulated on the success of his method, many of the pictures being perfect representations of bird life.

In the section of the work dealing with the Canaries, a very considerable portion of the text, as well as some of the illustrations, are devoted to the description of the country, its inhabitants and its buildings, so that it is only here and there natural history subjects are discussed at any length. There are, however, several excellent photographs of the nests and eggs of birds—notably the stone-curlew and the Egyptian vulture; and we may call especial attention to the pictures of a malachite sun-bird and its nest (Plate xxii) as first-rate examples of what can be done by photography in portraying the smaller types of bird-life.

In the second part of the volume, which treats of the author's experiences in South Africa, the bird-lover will find a very large amount of interesting matter. Personally, we have been much attracted by the author's account of his visit to Bird Island and St. Croix, two islets lying off Port Elizabeth. Apparently no one is allowed to visit these bird-haunted islets without a special permit, and an amusing story is told of the difficulty of obtaining such permission in this particular instance. Bird Island is the chosen resort of the Cape gannet, and the following account, illustrated by two photographs, gives a good idea of the numbers of these birds in the nesting season:—

"We rounded the north end of Bird Island first," writes Mr. Harris, "and then, close to the lighthouse, and covering quite an acre and a half of ground, were to be seen thousands of Cape gannets. The ground was white with the birds themselves, while above them in the air a kind of kaleidoscopic effect was produced by the ever-moving wings. Among a crowd of birds so thickly packed together as these gannets were, one naturally wonders if it is possible for them to keep to their own eggs; perhaps each bird recognises its own special place from the position of its neighbour. . . . The men at the lighthouse say that these birds arrive in a mass at this, their breeding season, and that when the season is finished the island is untenanted as to bird life until the following year. The spectacle was not so imposing as that presented by the gannets on the Bass Rock in Scotland, where the birds, as seen from a distance, have the appearance of bees swarming round a hive. Here the birds were shown horizontally instead of vertically."

Penguins are likewise abundant on these islands, and the author was fortunate in obtaining two photographs of these birds, in one of which they are shown swimming, and in the other standing on the rocks.

Perhaps the most interesting chapter in the whole book

[1] "Essays and Photographs. Some Birds of the Canary Islands and South Africa." By H. E. Harris. Pp. xvi+212. 8vo. Illustrated. (London: Porter, 1901.)

is the one describing the nesting habits of the two species of sand-plover which frequent the shore on False Bay and in the neighbourhood of Port Elizabeth. The visitor unaccustomed to the ways of these birds always fails at first to discover their eggs, although he may be convinced that they are in his immediate vicinity.

After one or two attempts, says the author, you retire and resolve to watch more carefully. "The bird soon returns to the same spot, shuffles for a second or two very quickly with its feet, and then sits down. This time you make no mistake about the exact place, and you locate the position of the bird with the aid of two little bits of herbage growing near; again you approach, the bird rises as before, and repeats the same performance, standing a little way off, and looking as though it would help you if it could, and if you would only tell it what you were looking for. The ground is quite undisturbed, and there is no sign of a nest or eggs; the little bits of driftwood and bark, though, which lie between your feet are loose, and the earth underneath them is loose also, and then you feel beneath the loose earth and there are two eggs!"

And yet it is difficult to account for this strange habit, since the eggs so closely resemble their surroundings that they would be passed unnoticed when lying on the bare ground. Often the nesting-site is in a locality much frequented both by men and cattle, and it is a marvel that all the eggs are not broken. On one occasion the author actually found an ox lying down on a nest whose situation was known to him; strange to say, although one egg was crushed, the other was intact. The proceedings of the parent bird while thus effectually prevented from obtaining access to her nest are described with some humour by the author.

Many other anecdotes might be culled from Mr. Harris's pages, but enough has been said to indicate the interesting character of his work and the large amount of information with regard to the habits of birds that it contains. The author has been fortunate in obtaining the assistance of Mr. Howard Saunders in revising the nomenclature, so that ornithologists may be satisfied that the various birds alluded to are correctly identified.

R. L.

Cape Gannets on Bird Island.

THE REPORT OF THE THOMPSON YATES LABORATORIES.

THE Thompson Yates Laboratories Report, lately published, edited by Profs. Rubert Boyce and C. S. Sherrington, is a worthy successor to the preceding volumes, which have previously been reviewed in these columns. The distribution of *B. coli commune* is the title of the first paper, by Miss Chick, who concludes that this organism is not so generally distributed as has been considered by some bacteriologists, and that its presence may be looked upon as useful evidence of recent fæcal contamination. Her experiments show the very low resistance which the *B. coli* can offer to unfavourable conditions, especially desiccation.

Mr. E. E. Glynn has investigated the relation between the *Bacillus enteritidis sporogenes* of Klein and diarrhœa. He has isolated this micro-organism from normal dejecta, dust, air, milk, and sugar, and has tested the effects of cultures upon guinea-pigs and upon himself by ingestion without evil result. He agrees with Dr. Hewlett that the *Bacillus enteritidis sporogenes* is a ubiquitous organism, and that there is at present no satisfactory evidence that it is a cause of diarrhœa.

Mr. A. T. MacConkey gives further details of his bile-salt lactose Agar medium for the isolation of *B. coli* and *B. typhosus*, for which purpose it seems to be a valuable addition to the methods hitherto in use. Mr. MacConkey also publishes a note on flagella staining, Mr. K. W. Monsarrat describes a primary malignant growth of the kidney, and Dr. Christophers discusses the prevention of malaria in Tropical Africa.

Enlargement of the spleen has been relied upon by many as the test of the prevalence of malaria in a district; but Dr. Daniels concludes that the spleen-test may be worse than useless unless race and age are taken into account.

FIG. 1.—Anopheles larvæ in several stages of their escape from the ova.

Two well-executed full-page diagrams by Messrs. Ross and Fielding-Ould illustrate the life-history of the parasites of malaria, while the last half of the volume is occupied with the Report of the Malaria Expedition to Nigeria of the Liverpool School of Tropical Medicine. The latter contains many good illustrations of the characteristics of the country and of the development of Anopheles. Two of these are here reproduced, one (Fig. 1) showing Anopheles as ovum and larva, the other (Fig. 2) a breeding-ground of Anopheles.

FIG. 2.—Portion of a cultivated area at Lokoja, showing butts and furrows, in the latter of which Anopheles puddles occur.

A portrait and short obituary notice of the late Dr. Myers and an illustration of the Kanthack Medal in Pathology also appear in this volume. All the papers are valuable contributions to the science of medicine, and we shall look forward with interest to the publication of future volumes.

R. T. H.

NOTES.

THE Cape papers, says the *Times*, report the formation at Cape Town of a "South African Association for the Advancement of Science," to work as far as possible on the lines of the British Association. In July last a meeting was held to establish a congress of engineers, when an influential committee was appointed. The proposal gradually widened until at length it was found feasible to establish a local "British Association," and a meeting for that purpose, held under the chairmanship of Sir David Gill, F.R.S., the Astronomer Royal at the Cape Observatory, was largely attended, and the formation of the Association having been decided upon by formal vote, the title was discussed, "South African" being carried by 31 votes against 19 for "African."

A REUTER telegram of October 14 from Cape Town states that the *Discovery* sailed that day from Simon's Bay for Lyttelton, New Zealand.

THE resignation of Dr. John Young, professor of natural history and lecturer in geology in the University of Glasgow, is announced. Dr. Young, who was appointed in 1866 to the professorship he now vacates, will retain his connection with the Hunterian Museum, of which he has for a number of years been curator.

PROF. JOHN JOLY, F.R.S., has, subject to the approval of the Lord Lieutenant, been co-opted to fill the vacancy on the Irish Lights Board caused by the death of Mr. J. Pim.

MR. J. R. JACKSON, who for a period of forty-three years has been associated with the Royal Gardens, Kew, has resigned the keepership of the Museum of Economic Botany, and is succeeded by Mr. J. M. Hillier, whose place, in turn, has been taken by Mr. J. H. Holland, late of the botanic station at Old Calabar.

THE death is announced in the Allahabad *Pioneer Mail* of Dr. Vonkrafft, of the Geological Survey of India, who was appointed to India by the Secretary of State and has, since January, 1899, been mainly employed in the Himalayas.

THE fiftieth scientific anniversary of M. Berthelot (he began his career as a chemist in 1851) is to be commemorated, says the *Chemist and Druggist*, by the presentation to him next month of a metal plaquette by his colleagues of the Institute of France. On the front of the plate, which is the work of Chaplin, the engraver, the recipient's portrait will be reproduced in profile, and on the back M. Berthelot will be portrayed seated at his laboratory table, "Truth" illuminating him with a torch, and "Patrie" protecting him under a flag and offering him a crown of laurels.

THE first Egyptian Medical Congress will be held in Cairo, under the presidency of Dr. Ibrahim Pacha Hassan, from December 10 to 14 next.

AN Industrial and Art Exhibition will be held at Düsseldorf next year, and already the intending exhibitors number about 2300. The exhibition will embrace the following groups:—mines and saltworks; smelting works; the metal industry; machinery and electrical engineering; transport; chemical industry; articles of food, &c., and apparatus for preparing them; stone, earthenware, porcelain, cement and glassware; the wood and furniture industries, house decoration, &c.; fancy goods and small wares; the textile industry; clothing trades; leather, indiarubber and asbestos goods; the paper trade; the printing trade; scientific instruments; building and engineering; education; hygiene and benevolent institutions; sport; horticulture; agriculture and forestry; and art. As was the case with the Paris Exhibition of 1900, a large number of international and other congresses will be held at Düsseldorf during the exhibition.

THE general committee of the Photographic Salon will hold an "At Home" at the Dudley Gallery, Egyptian Hall, on Tuesday next, at 8.30 p.m.

THE next meeting of the Institution of Mechanical Engineers will be held to-morrow, the 18th inst., when Prof. Burstall will present the second report to the Gas-Engine Research Committee. At the November meeting of the Institution a paper will be read by Prof. Dalby on the balancing of locomotives.

A REUTER telegram from St. Petersburg states that a letter has been published in the *Turkestanskiya Viedomosti* giving the following information concerning Dr. Sven Hedin, the Swedish traveller, based upon a letter from him, dated July 10. It appears that Dr. Sven Hedin, at the time of the despatch of the letter, was at the foot of the Akka Tagh, in Northern Tibet, and intended to proceed in the direction of Ladak in order to survey accurately the region about the source of the Indus. Next spring he proposes to return to Osh *via* Kashgar. Meanwhile, a caravan of fifteen horses has arrived at Kashgar bringing the results of two years of the traveller's work in the shape of scientific collections, maps, photographs and diaries. Dr. Sven Hedin speaks in the highest terms of his Cossack escort and extols their courage, endurance and resource in critical situations. Up to the time of writing he had been in no way molested by the Chinese.

THE Liverpool School of Tropical Medicine, according to a Reuter telegram, has now completed the necessary arrangements for the despatch of an expedition at once to the Gold Coast, and to the mining districts there. Dr. Charles Balfour Stewart, under whose leadership the expedition will be, leaves for West Africa this month. He first proceeds to Sierra Leone in order to study the methods now being employed there with such success by Dr. Logan Taylor. After leaving Freetown, Dr. Stewart will go at once to Cape Coast Castle to attack the insanitary conditions there, as the mortality amongst the Europeans in that town is at present most serious. He is to adopt, under Major Ross's general direction, the latest methods known to science for obtaining the end in view, and will employ large gangs of workmen for draining the ground and clearing the houses of broken water vessels and otherwise attacking the breeding-grounds of the mosquitoes. As regards the movements of the expedition, these, to a great extent, will be determined by the Governor, Major Nathan, with whom Major Ross had a personal interview on the Gold Coast two months ago, when the Governor promised the expedition most valuable assistance. The expedition has been rendered possible owing to the generosity of a private individual who desires to remain anonymous. Anti-malarial operations will shortly be in full swing in the Gambia, Sierra Leone, the Gold Coast, and Lagos, the operations in the three first named colonies being organised by and under the complete control of the Liverpool School of Tropical Medicine.

IT has been decided that the house which Prof. O. C. Marsh bequeathed to Yale University shall in future be known officially as Marsh Hall, and the grounds in connection with it as the Yale Botanical Garden.

THE subject of the Fiske Fund Prize Essay (value 200 dollars) for the year 1902 is, says *Science*, "Serumtherapy in the Light of the most recent Investigations." The secretary of the board of trustees of the Fund, from whom all necessary information may be obtained, is Dr. H. De Wolf, 212, Benefit-street, Providence, R.I., U.S.A.

THE following awards have been made by the Institution of Civil Engineers for papers dealt with in 1900–1901:—A Telford Medal and Premium to R. P. Bolton; a Watt Medal and a Telford Premium to J. E. Dowson; a George Stephenson Medal and a Telford Premium to W. T. C. Beckett; a Manby Premium to E. K. Scott; a Trevithick Premium to T. A. Hearson; a Telford Premium to J. A. W. Peacock. For students' papers the awards are:—A Miller Scholarship (tenable for three years) and the James Forrest Medal to E. V. Clark; Miller Prizes to C. E. Inglis, H. E. Wimperis, J. L. Cridlan, F. K. Peach, G. H. Whigham, F. Taylor, A. C. Walsh and H. O. Jones.

A NUMBER of awards are to be made by the Industrial Society of Mülhausen, in 1902, among which the following may be noted:—A medal of honour and 400–800 marks, according to the value, for a handbook consisting of tables giving the density of the greatest possible number of mineral and organic combinations in crystal form and in saturated cold solutions. The solution-capacity at other temperatures is to be added to the work as a supplement. A silver medal for the synthesis of a product possessing the most important qualities of Senegal gum capable of use in textile industries. A medal of honour and 800 marks for a substance which may be used as a cheaper, substitute for dry egg-albumen in the printing of fabrics. A medal of honour and 800 marks for a colourless blood-albumen which will not become coloured when steamed. A silver medal for a handbook treating of the analysis of the drugs used in calico-printing and in dyeing. A silver medal for an ink which can be used for marking woollen fabrics to be dyed red, brown, or any other dark colour. This ink must remain visible after all the dyeing processes. A silver medal for a practical process of removing spots of mineral-fat from fabrics. A silver medal for a treatise on the preparation of hydrogen peroxide, and its application for bleaching textile fabrics. For these prizes foreigners are allowed to compete. All drawings, samples, &c. should be marked with a motto and sent before February 15, 1902, accompanied by a sealed envelope containing the name and address of the competitor, to the Präsidenten der Industriellen Gesellschaft, Mülhausen, Alsace.

PRIZES are offered by the English Arboricultural Society for the best essays on the following subjects:—The more extensive cultivation of hardy flowering shrubs; the arboricultural management of private and public parks; an essay on any insect or group of insects injurious to forest trees; the natural regeneration of oak and beech woods; on the management of young trees, with the view of rendering them suitable for planting in avenues, streets and other places; the relative durability of British-grown exotic trees; on the growth and freedom from disease in this country of larches, other than the common European larch; the financial aspect of forestry, with special reference to actual cases. In addition to the foregoing, Mr. H. J. Elwes, F.R.S., offers a special prize for a paper on natural reproduction of trees by seed in England. The next annual meeting of the Society will be held in France.

THE following gentlemen have been nominated to serve on the council of the London Mathematical Society for the ensuing session:—President, Dr. Hobson; vice-presidents, Prof. W. Burnside and Major MacMahon, R.A.; treasurer, Dr. J. Larmor; hon. secs., R. Tucker and Prof. Love; other members, J. E. Campbell, Lieut.-Colonel Cunningham, R.E., Prof. Elliott, Dr. Glaisher, Prof. M. J. M. Hill, H. M. Macdonald, Prof. L. J. Rogers*, A. E. Western, E. T. Whittaker and A. Young*. Those marked * are new nominations. The retiring members are Lord Kelvin and Mr. A. B. Kempe. The annual meeting will be held at 22, Albemarle-street, W., on November 14, at 5.30 o'clock.

EXPERIMENTS have recently been made in the State of Connecticut for the purpose of cultivating the Sumatra tobacco plant. It is stated that the experiments have been very successful, and great interest is now being taken in the matter in order to improve the quality of the Connecticut leaf, which is much used as a wrapper for the better quality cigars.

MAJOR RONALD ROSS informs the *British Medical Journal* that he has recently received a communication from a Jamaica correspondent drawing his attention to the fact that mosquitoes are responsive to certain sounds, such as a continuous whoop or hum. Major Ross's informant states that swarms gather round his head when he makes a continuous whoop. There may be, however, he says, some particular note or pitch that would be more attractive to them.

AT the recent meeting of the American Association, in the Section of Chemistry, Prof. J. H. Long, president of the section, delivered an interesting address on the teaching of chemistry in the medical schools of the United States. The first part of the address was devoted to sketching historically the teaching of chemistry in the American medical schools. A prominent individuality in this connection was Dr. Robert Hare, whose great merit apparently consisted in the ingenuity he displayed in contriving experiments to illustrate simple chemical principles to medical students. While Hare was prominent in Philadelphia, Silliman, Gorham and Mitchell were developing the departments of medical chemistry in Yale, Harvard and Columbia. The next step in the teaching of chemistry to medical students was the institution of laboratory courses; this did not take place at Harvard until 1872. Subsequently to this an important question arose as to the qualification of the teacher of so-called medical chemistry. Since, formerly, the main use of chemistry to the medical student lay in its direct application to pharmacy it was held that this subject was best taught by a physician; the growth, however, of physiological chemistry, and the obvious relation of chemical principles to physiology and pathology, rendered it of the first importance that medical students should be well grounded, not only in the properties of isolated substances as heretofore, but in the actual principles of organic and inorganic chemistry. A trained chemist alone was competent to teach upon these lines, and hence the medical chemistry taught by the physician became replaced by chemistry taught by a chemist. The remainder of Prof. Long's address dealt with the far-reaching importance of chemistry, inorganic as well as organic, to the medical student, and the inadequacy of mere analytical courses, into which there is apparently some danger of the teaching of chemistry degenerating. He emphasises the fact, well recognised in this country, that the burning problems of the physiology, the pathology and therapeutics, if not of to-day, certainly of the near future, are essentially chemical, and instancing the work of Bredig upon the fermentative action of colloidal platinum, &c., points out that they are by no means necessarily confined within the accepted limits of so-called organic chemistry.

THE Imperial Department of Agriculture for the West Indies maintains its activity in supplying the colonists with the most trustworthy information bearing upon the various subsidiary industries which should, with a little energy and patience, bring about a great improvement in the welfare of the islands. Pamphlet Series, No. 9, now being distributed, deals with "Bee-Keeping in the West Indies." In Europe and America there is a large and ever-increasing demand for honey and beeswax, yet the West Indian islands, with their dozens of varieties of honey-bearing flowers all round the year, may be said, with the exception of Jamaica, to have thus far made no real attempt to regard bee-keeping as worthy of encouragement. Mr. W. K. Morrison, formerly of the United States Department of Agriculture, has been engaged by Dr. Morris as expert adviser to the Imperial Department, and he has been touring amongst the islands during the first half of the present year studying the conditions and prospects of bee-keeping. The outcome of his investigation is this pamphlet of 73 pages, conveying to all who wish to increase their income in an easy manner simple hints and suggestions as to the requirements of tropical bee-keepers. Only a small capital is required to make a good start, and the profits are large so long as a sound and attractive article is produced. It is indicative of the natural carelessness of the colonists that it should be considered necessary to dwell upon this weakness, for in insisting that a high standard of excellence is required to secure remunerative prices on the European markets, it is added that "The great danger to West Indian bee-keeping will probably lie in the tendency to ship abroad honey or wax of an inferior quality." The pamphlet, which is illustrated, is a veritable storehouse of instruction, and should be the means of originating an industry which may add considerably to the wealth of the islands.

PROF. T. LEVI CIVITA, writing in the *Atti dei Lincei*, discusses the law of fluid resistance, and in particular the property that this resistance varies approximately as the square of the velocity, as a consequence of the properties of discontinuous motion in a perfect fluid. The author obtains for the most general case an expression for the resistance in the form of a series of even powers of the velocity, which series is convergent for velocities below a certain limit, and in the cases commonly occurring in practice reduces approximately to its first term, giving Newton's law.

IN a recent *Bulletin* of the Agricultural College at Tokyo there is an investigation by Mr. Aso on the causes of the difference in colour between green and black tea. In making green tea the leaves are steamed as soon as gathered; in the case of black tea the leaves are allowed to ferment before drying. The finished black tea contains much less tannin than the green. The author shows that the original tea-leaf contains an oxidising enzyme, which is destroyed by heating to about 77° C. During the fermentation of the leaf in the manufacture of black tea this enzyme oxidises the tannin, giving rise to a brown product.

THE June issue of the *Monthly Weather Review* of the U.S. Weather Bureau has a note stating that an observer at Tillers Ferry, South Carolina, had reported that during a heavy local rain in June there fell hundreds of small fish (cat, perch, trout, &c.), which were afterwards found swimming in the pools between the cotton rows in a field. "It is," says the *Review*, "a well-known fact that in such rains all sorts of foreign objects, whether sticks or stones, frogs or fish, or even débris of destroyed houses and crops, occur occasionally, not only in America, but in Europe and elsewhere. It is very rare that we are able to trace these objects back to their sources, but there can be no reasonable doubt that they were carried up from the ground by violent winds, such as attend thunderstorms and tornadoes."

INTERNATIONAL balloon ascents (both manned and unmanned) were undertaken by several countries on July 4 and August 1. The greatest heights at which records were obtained in July were at Trappes, near Paris, 10,270 metres, temperature −52° C. (on ground 16°·5), and at Chalais Meudon, 10,260 metres, temperature −43° (on ground 16°·7). In August, the greatest heights at which observations were recorded were:—Trappes, 9800 m., temperature −40° (on ground 17°·5); Berlin (July 31), 13,040 m., temperature −48° (on ground 15°·1). Drs. Berson and Suring reached an altitude of 10,300 m., temperature −40°. At Vienna a temperature of −33° was recorded n an unmanned balloon at a height of 10,000 metres.

AN agreement has just been concluded between Marconi's International Marine Communication Co., Ltd., and Lloyd's, by which the latter agree to employ no system of wireless telegraphy other than the "Marconi" for a period of fourteen years. The agreement also provides for the immediate equipment of ten Lloyd's signalling stations, one of which is to be on the Fastnet Rock and two on the Red Sea coast, together with the taking over of some of the existing British stations, of which there are at present eight, that could be rendered serviceable to Lloyd's for mercantile signalling.

THE *Monist* for October contains the translation of a paper by Prof. Ludwig Boltzmann on the necessity of atomic theories in physics. In it the author compares the atomic theory with the second method, which seeks to represent the facts of physics by means of differential equations; the latter method he calls "mathematico-physical phenomenology." The object of the paper is to discuss the advantages arising from the retention of the atomic theory, and its claims to be studied at least in parallel with the phenomenologic method. Even if it should be possible to formulate an all-embracing theory of the world, every feature of which has the same evidence as Fourier's theory of the conduction of heat, Prof. Boltzmann thinks it is still an open question whether such a theory can be more easily reached through atomism or phenomenology. It would even be permissible to assume that several representations of the universe, each possessing the ideal traits, were possible.

A SINGLE bone of the wing, and that imperfect, may nowadays seem but poor material on which to establish a new genus of birds, but Dr. F. A. Lucas (*Proc. U.S. Mus.*, vol. xxiv. No. 1245) appears to be justified in regarding a humerus from the Miocene of Los Angeles, California, as representing a large extinct type of flightless auk. For this the name *Mancalla californiensis* is suggested; it is considered to have equalled the great auk in size, but to have been more nearly allied to the guillemot. The existence of a flightless member of the group at such a comparatively early epoch is considered remarkable. In the same journal Messrs. Jordan aud Snyder continue their review of the fishes of Japan, dealing in No. 1241 with the hypostomid and lophobranchiate types, and in No. 1244 with the gobies, of which no less than twenty-one species are described as new. No. 1242 of the journal in question contains Mr. R. V. Chamberlin's account of myriopods of the Lithobius group, while No. 1243 is devoted to the description of new flies from Southern Africa, by Mr. D. M. Coquillett.

THE development of the typical flies (Muscidæ) forms the subject of an elaborate investigation by Herr W. Noack, the results of which are published in the latest issue of the *Zeitschrift f. Wissenschaft. Zoologie* (vol. lxx. part i.). No less than eight distinct stages in developmental history are recognised. In another article in the same issue Herr J. Schaffer, of Vienna, commences a dissertation on the histology and development of cartilaginous structure, and the various modifications assumed by that substance.

SOME time ago Dr. D. G. Elliot's "Synopsis of North American Mammals" (*Field Museum Publications*) was noticed in our columns. The author has supplemented this with a "list" of the mammals of the same area (*Field Mus.—Zool.* vol. ii. No. 2), which contains a few names omitted from the larger work, together with some published too late for inclusion in the latter, and such emendations as have been found necessary. In the same journal (vol. iii. No. 5) Dr. Elliot describes and figures the reindeer, or caribou, of the Kenai Peninsula, Alaska—the *Rangifer stonei* of Dr. J. Allen—in the course of which he throws doubts on the distinctness of this form, and suggests that the American reindeer have been too much subdivided by recent writers.

IN accordance with a recent decision of the council, the first part has been issued of "Obituary Notices of Fellows of the Royal Society." It contains the biographies of recently deceased Fellows, reprinted from the year books for 1900 and 1901, together with an index to the obituary notices previously published in the Society's *Proceedings*.

IN their new catalogue, Messrs. C. Baker, of High Holborn, announce that they have arranged a series of free demonstrations during the coming session, illustrating the use of apparatus for the illumination of microscopic objects, testing of objectives, micrometry and drawing with the microscope. Another announcement of some interest refers to the microscopic slide-lending department, which has now been placed in the hands of various specialists, who have prepared type-written descriptions of most of the series of objects sent out; these should considerably increase the educational value of the system. Of other items we may cite a new engineering microscope (for examining metals) and a mosquito-collecting outfit (for malarial observations), as illustrating the large variety of apparatus now supplied to meet the requirements of modern specialisation.

HANN'S "Lehrbuch der Meteorologie" (Tauchnitz) is now complete. It consists of 10 Lieferungen instead of 8, as was originally proposed.

A PRACTICAL journal for amateur gardeners has just made its appearance under the title of *Garden Life*. The journal informs horticulturists what to do and how to do it, but it mostly leaves the reasons for the operations out of consideration. We suggest that there is a science as well as an art of horticulture, and that descriptions of simple experiments in the physiology of plants, or studies of plant diseases, might be included in the contents of future numbers.

SOME specimen copies of the *Boletim mensal* of the Observatory of Rio de Janeiro have been forwarded to us by the director. These bulletins contain useful meteorological *résumés* collected from various sources in Brazil for a series of years, and tables of the observations made several times daily at the Observatory. There are also occasional climatological sketches referring to other parts of the world.

THE September issue of *The Scientific Roll* (Bacteria) has reached us, and contains a mass of references to books and papers dealing with bacteriology. An editorial note states that although the list is fuller than any other published, it still has many omissions, and bacteriologists who find in it no mention of their contributions are reminded that the remedy is in their own hands, and are invited to send to the conductor the titles and other particulars of the books and articles they have published, that the same may be noted.

THAT well-produced periodical the *Reliquary and Illustrated Archaeologist* always contains some articles of scientific interest, and the issue for October is no exception to the rule. Mr. John Ward, of the Cardiff Museum, describes the interesting "Five Wells Tumulus" in Derbyshire, and another article of note is that by Mr. W. J. Wintemberg, dealing with "Drills and Drilling Methods of the Canadian Indians." Both papers are suitably illustrated.

THE additions to the Zoological Society's Gardens during the past week include a Tantalus Monkey (*Cercopithecus tantalus*) from Africa, presented by Sergeant T. Golding; a White-throated Capuchin (*Cebus hypoleucus*) from Central America, presented by Mr. C. E. Engelbach; a Kinkajou (*Cercoleptes caudivolvulus*) from South America, presented by Mr. W. B. Hall; a Suricate (*Suricata tetradactyla*) from South Africa, presented by Mrs. Lester; two Indian Crows (*Corvus splendens*) from India, presented by Mr. Boyek; a Macaque Monkey (*Macacus cynomolgus*) from India, a Parry's Kangaroo (*Macropus parryi*, ♀), four Musky Lorikeets (*Glossopsittacus concinnus*), a Turquoisine Parrakeet (*Neophema pulchella*) from Australia, deposited; a Gouldian Grass Finch (*Poëphila gouldiae*), a Beautiful Grass Finch (*Poëphila mirabilis*) from Australia, purchased.

OUR ASTRONOMICAL COLUMN.

THE SPECTROSCOPIC BINARY η PEGASI.—Observations of this interesting spectroscopic binary, discovered by means of the Mills spectrograph in August, 1898, have now extended over more than two complete periods, and Prof. Campbell has recently issued the data obtained from the reduction of the measures. Twenty-nine photographs, extending from 1896 August 27 to 1901 May 9, have been utilised in the determination of the orbit.

Elements of Orbit, η Pegasi.

$$
\begin{aligned}
K &= 14{\cdot}20 \text{ km.} \pm 0{\cdot}13 \text{ km.}\\
e &= 0{\cdot}1548 \pm 0{\cdot}0106.\\
\omega &= 5^\circ{\cdot}605 \pm 3^\circ{\cdot}708.\\
\mu &= 0{\cdot}007681 \text{ rad.} \pm 0{\cdot}000020 \text{ rad.}\\
&= 0^\circ{\cdot}44009 \pm 0^\circ{\cdot}00117.\\
T &= 1898 \text{ June } 29{\cdot}7 \pm 8{\cdot}1 \text{ days.}\\
&= 1901 \text{ September } 25{\cdot}7.\\
V_0 &= +4{\cdot}31 \text{ km.} \pm 0{\cdot}10 \text{ km.}\\
U &= 818{\cdot}0 \text{ days} \pm 2{\cdot}2 \text{ days.}\\
a \sin i &= 157{,}800{,}000.
\end{aligned}
$$

A light curve embodying the above is given, from which it is found that the maximum velocity is $+20{\cdot}70$ km. per second, and the minimum $-7{\cdot}70$ km. per second.

The star has been carefully examined with the 36-inch refractor, but no indication of the companion star is to be seen (*Lick Observatory Bulletin*, No. 5).

THE HAMBURG MEETING OF THE GERMAN ASSOCIATION.

THE seventy-third meeting of the German Association of Naturalists and Medical Men lately held at Hamburg was an unusually successful gathering. It will be remembered that it was the existence of this institution which suggested the foundation of our British Association, the latter being only a few years junior to the former. Though otherwise alike, the two associations nevertheless differ in some important respects, especially in the fact that the German body still unites with its purely scientific work functions performed here by the British Medical Association. Another notable difference lies in the fact that presidential addresses, which form so important a feature with us, are not delivered at the German congress. There are, moreover, no popular lectures of any kind, and it is understood that no one shall attend sectional meetings who is not professionally interested in the matters discussed. A good attendance of men of science is further promoted by the fact that it is the custom of some of the learned societies of Germany to hold their annual meetings in connection with this congress.

The meeting just concluded was formally opened on Monday, September 22, in the great Concerthaus, under the presidency of Prof. Richard Hertwig (Munich). On behalf of the municipality of Hamburg, speeches of welcome were delivered by Prof. Voller, Dr. Hartmann and Prof. von Neumayer, to which the president responded. After these proceedings Prof. Lecher (Prag) delivered an address on the discoveries of Hertz and their subsequent developments, reminding the audience that Hertz was a Hamburg man and that his work was most appropriately taken for the first consideration of the congress. A lecture from Prof. Hoffmeister was to have followed, but illness prevented him from attending. Prof. Boveri (Würzburg) then lectured on the problem of fertilisation, giving a lucid account of the phenomena in a considerable number of organisms, and concluding with an emphatic pronouncement that fertilisation in its essence must not be regarded as the cause of the development of the ovum, but rather as a means whereby certain organisms are enabled to combine in one body the characters of distinct individuals.

The congress then broke up into sections, of which eleven were devoted to the natural sciences and sixteen to medical subjects, physiology being included with the latter. Prof. van 't Hoff acted as president of the scientific, and Prof. Naunyn as president of the medical groups respectively. The division of the scientific subjects differs somewhat from that followed with us, the sections being constituted thus:—Mathematics, Physics, Applied Mathematics, Chemistry, Applied Chemistry, Physical Geography, Geography, Geology with Mineralogy, Botany, Zoology, Anthropology. For the consideration of these sections some hundreds of papers were provided.

On Wednesday the congress met in a second general session to hear a group of papers on recent developments of the atomic theory, namely, Prof. Kaufmann (Göttingen), on the development of the conception of electrons; Prof. Geitel (Wolfenbüttel) on the bearing of the theory of gas-ions on the phenomena of atmospheric electricity; Prof. Paul (Tübingen), the significance of the theory of ions in physiological chemistry; Prof. His, jun. (Leipzig), the significance of the theory of ions in clinical medicine. On the following day the medical group combined in a general meeting to receive an address from Prof. Ehrlich, of Frankfurt-a-M., on the protective substances of the blood. Prof. Gruber (Vienna), who was to have lectured on the same subject, was unavoidably absent. On the same morning a joint meeting of the scientific group assembled with Prof. van 't Hoff in the chair. The first paper was by Prof. Ostwald (Leipzig) on catalysis, giving an account of his hypothesis, or as he preferred to call it "protothesis," regarding the mode of action of catalysers, accompanied by some beautiful demonstrations. This was followed by a group of papers relating to the present position of the doctrine of organic descent. Prof. de Vries, of Amsterdam, opened with a discourse on the action of mutations and mutation-periods in the origin of species. He gave an account of his lately published experiments with *Œnothera Lamarckiana*, showing how this single species is annually splitting up into some seven constant forms which he regards as distinct species. He proceeded to suggest lines on which an attempt might be made to compute the whole number of mutations which have gone to the formation of an existing species. He was followed by Prof. Koken (Tübingen), on palæontology and the theory of descent, and Prof. Ziegler (Jena), on the present position of this theory in zoology.

On Friday another general meeting of the whole congress was addressed by Prof. Curschmann (Leipzig), on medical science in connection with the shipping industry; by Prof. Nernst (Göttingen), on the use of electrical theories and methods in chemistry; and by Prof. Reinke (Kiel), on the natural forces at work in organisms.

Several important joint meetings of two or more sections also took place, notably of the biological sections, to discuss the position of biological teaching in schools, the subject being opened by Dr. Ahlborn, of Hamburg. In this discussion Profs. Reinke, Waldeyer, Heincke, R. Hertwig, Chun and others took part, and a committee was formed to consider the matter further. The same sections also were addressed by Prof. R. Hertwig, on the cell theory, Prof. Reinke, on cells without nuclei, and by Prof. Correns, of Tübingen, on recent discoveries in hybridisation and their bearing on theories of heredity. In connection with the latter paper the author exhibited a remarkable series of specimens illustrating the Mendelian laws of heredity. Joint meetings of the physical and chemical sections also took place to hear papers by Profs. Schilling (Göttingen), Charlier (Lund), Halm (Edinburgh), Simon (Frankfurt), Geitel (Wolfenbüttel), Abegg (Breslau), Hantsch (Würzburg), Wegscheider (Vienna), and many others. The medical and physiological sections had a no less extensive programme, a special feature being a joint meeting in the Concerthaus to receive an address by Prof. Kronecker (Berne) on the innervation of the mammalian heart.

Other meetings of considerable importance were those of the Tuberculosis Committee, under the chairmanship of Prof. Hueppe (Prag). Among the long series of papers read may be mentioned a communication by Dr. Grünbaum, of Liverpool, made on behalf of Prof. Boyce and himself, to the effect that positive evidence had been obtained by them that bovine tuberculosis could be communicated to the chimpanzee.

Besides the meetings and demonstrations some interesting exhibitions had been organised, amongst others displays of chemical, physical and surgical apparatus, a series of demonstrations of Röntgen-ray apparatus, of the methods of colour-photography, &c. The museums and other scientific and medical institutions of Hamburg were open throughout the week to members of the congress. As of special interest to naturalists may be named the novel preparations of Dr. Michaelsen, showing by means of artificial spirit-aquariums the modes of life of molluscs, worms and other marine organisms. In the Zoological Garden were exhibited the skeleton and stuffed skin of the gigantic gorilla lately brought from the Cameroons, and bought for the Tring Museum. This specimen, which stands some 6 feet high, is believed to be the finest in Europe. On Friday a special visit was made to the new institution for preventing the introduction of agricultural pests. This is the only institute of the kind in the world excepting that in New York. In it an attempt is made to disinfect all fruit and vegetable produce coming to the port of Hamburg, and thus to check the spread of exotic pests.

Each member was presented with a guide-book and with a large quarto treatise of 600 pp. describing and illustrating the natural history of the district, its scientific institutions and resources, similar treatises on the medical and hygienic institutions being in addition presented to the medical members. Each member also received a silver medallion-badge of great artistic distinction specially designed by Herr Illies.

The festivities organised and for the most part provided by the municipality and by residents in Hamburg were on an unusually magnificent scale, far exceeding anything of the kind that had been done before, and probably these evidences of the wonderful prosperity of the great free town will be to the foreign visitor among the most lasting memories of the meeting.

On Sunday, before the congress officially began, the members were invited to see a procession of boats dressed in flowers, which rowed round the inland waters of the Ausser Alster, the entertainment concluding with fireworks on the lake. On Monday the Zoological Garden was illuminated. On Tuesday some 1300 members of the congress were received by the Burgomaster and Senate of Hamburg and entertained at supper in the princely suites of rooms composing the new Rathhaus, while the remainder were invited by the directors of the Hamburg-America line to a similar entertainment on board two of the company's largest vessels. A "Festessen" took place in the Zoological Garden on the following day, at which some 1500 dined simultaneously. On Thursday a concert was provided, followed by a ball, and on Friday the whole congress was conveyed down the river in five large steamers to Blankenese, returning after dark to see the illuminations which had been arrayed along the whole length of the Elbe. Later in the evening those who were not quite exhausted returned to the Concerthaus to take part in further proceedings of a hilarious character and to listen to speeches of farewell.

On the following day the congress broke up, some joining an excursion to Heligoland, while a larger number went on a two days' expedition to Kiel, Lübeck and other places of interest.

The organisation was brought to the highest possible point of efficiency, and most of the office work throughout the meeting was patiently supplied by volunteers. Provision for the comfort of visitors went even so far as to fill the incoming trains with maps of the town and printed information on all practical matters, and students were waiting on the platforms to find lodgings for and to direct those who might need such help. The number of those who became members for the meeting is said to have exceeded 3000, about 1000 being lady-associates. For the latter, separate entertainments of various kinds were organised on a lavish scale, to take place each day during the scientific business.

It was announced that the meeting for next year will be held at Karlsbad under the presidency of Prof. Chiari, of Prag, with Prof. Selenka and Prof. Stintzing as presidents of the scientific and medical groups, respectively.

PRIZES FOR RESEARCHES IN MEDICAL SCIENCE.

THE issue of the *British Medical Journal* for August 31 is the annual educational number, in which particulars are given as to the medical curriculum, the ways to degrees or other qualifications, and the various medical schools. This number and that of September 7 contain a few particulars as to open scholarships and prizes which are awarded for the purpose of assisting investigations in various subjects connected with medicine, or for researches actually accomplished. The assistance to scientific work given by the Royal Society and the British Medical Association is too well known to make any description of it necessary, but the following statement, abridged from our contemporary, contains mention of many prizes for research not generally known to exist, some of which confer distinction far beyond their monetary value.

The Weber-Parkes Prize is awarded by the Royal College of Physicians every third year for an essay on some subject connected with the etiology, prevention, pathology, or treatment of tuberculosis, especially with reference to pulmonary consumption in man. The prize consists of 150 guineas and a silver medal. A similar medal is also awarded to the essayist who comes next in order of merit. There was no award made in 1900.

The Jacksonian Prize of the Royal College of Surgeons is open to Fellows or members of the College. Its annual value is about 12*l*. For 1901 the subject for the prize is the diagnosis and treatment of bullet wounds of the chest.

The Astley Cooper Prize is a triennial prize of the value of 300*l*., which will be next awarded in 1904 for the best essay on the pathology of carcinoma and the distribution and frequency of occurrence of the secondary deposits, corresponding to the various primary growths. The essays must contain an account of original experiments and observations not already published, and be illustrated as far as possible by preparations and drawings.

The William F. Jenks Memorial Prize is given triennially by the College of Physicians of Philadelphia for the best essay on some announced gynæcological or obstetrical subject. It is of the value of about 100*l*. The essays are to be sent to the Chairman of the Prize Committee, from whom full particulars may be obtained. The last award was in January, 1901.

The three following prizes are given for essays on subjects connected with tropical diseases, which must be sent to the editors of the *Journal of Tropical Medicine* not later than December 7, 1901. An essay on the duration of the latency of malaria after primary infection as proved by tertian or quartan periodicity or demonstration of the parasite in the blood, for the Sivewright Prize; on the spread of plague from rat to rat and from rat to man by the rat-flea, for the Belilios Prize; and on the best method of administration of quinine as a preventive of malarial fever, for the Lady Macgregor Prize.

The Carmichael Prize is in the award of the President and Council of the Royal College of Surgeons in Ireland. It is of the value of 120*l.*, and is given for the best essay dealing with the state of the medical profession in Great Britain and Ireland.

The British Medical Association has instituted two Research Scholarships, awarded annually but capable of being continued for three years, each of the yearly value of 150*l.* These are for the encouragement of research in anatomy, physiology, pathology, bacteriology, State Medicine, clinical medicine, and clinical surgery. They are awarded by the Council of the Association on the recommendation of the Scientific Grants Committee.

The Association has also established an Ernest Hart Memorial Scholarship of the annual value of 200*l.*, the holder of which is required to devote himself to the study of some subject in the department of State Medicine. Forms of application for these scholarships may be obtained from the General Secretary of the Association.

The Grocers' Company have instituted three Medical Research Scholarships, open to all British subjects, of the annual value of 250*l.* They are intended as an encouragement to the making of exact researches into the causes and prevention of important diseases.

At Cambridge there are at least two valuable studentships in science, each of the annual value of 200*l.* and tenable for three years. One is the Balfour Studentship for original research in biology, and especially in animal morphology; and the other the John Lucas Walker Studentship for original research in pathology. At Trinity College the Coutts Trotter Studentship is open in physiology and experimental physics.

In connection with the Jenner Institute of Preventive Medicine a studentship of the value of 150*l.* has been offered. It is open to all British, including Colonial, subjects; it is tenable for one year and is renewable for a second year. It has been instituted for the purpose of research in pathological chemistry.

The Salters' Company Research Fellowship, of the annual value of 100*l.*, is for the promotion of research in pharmacology. It is awarded by the Company on the nomination of the treasurer of St. Thomas's Hospital and a Committee of Selection. It may be held for a term of three years, and the research must be prosecuted in the laboratories of St. Thomas's Hospital.

In connection with University College, Liverpool, are the Alexandra Fellowship in pathology, which was instituted in 1899 for a period of five years, and is of the annual value of 100*l.*; and the Colonial Fellowship in pathology and bacteriology, for which there is a preference for members of Colonial universities and medical schools.

The Walker Prize of the Royal College of Surgeons is awarded every five years for the best work in advancing the knowledge of the pathology and therapeutics of cancer. It is of the value of 100*l.* It is open to foreigners as well as British subjects, and it is not intended that essays should be written specially for the competition.

The John Tomes Prize is awarded triennially by the Royal College of Surgeons for original work on dental surgery, pathology, anatomy, physiology, or mechanics. The next award is for the period ending December 31, 1902.

The Cameron Prize, which is of the value of about 100*l.*, is given annually by the University of Edinburgh to the member of the medical profession who shall be adjudged to have made the most valuable addition to medical therapeutics during the year preceding.

The Marshall Hall Prize is given every five years by the Royal Medical and Chirurgical Society for physiological and pathological researches relating to the nervous system.

The Alvarenga Prize of the College of Physicians of Philadelphia, of the value of 36*l.*, is awarded annually for the best essay on any subject in medicine not already published. The essays, bearing a motto but no name, are to be sent to the secretary on or before May 1 of each year, and the award is made about July 14 following. A second is given by the Académie de Médicine in Paris, and a third by the Hufeland Society in Berlin, a fourth in Belgium, and a fifth by the Misericordia Hospital of Lisbon.

The Riberi Prize, which is of the value of 800*l.*, is offered by the Royal Medical Academy of Turin for original work in anatomy, physiology, pathology, or pharmacology. Research on the history of medicine since the Renaissance may also be submitted. The account of the research must be written in Latin, French, or Italian, and is to be sent to the secretary of the Academy. The prize is awarded for work done during the previous five years, and the last award was made in 1897.

The Bressa Prize of the Royal Academy of Science, Turin, is of the value of about 400*l.*, and is given for the most important scientific work produced during a given term of years. The last award was made in 1899.

The Vallauri Prize, of the value of 1,200*l.*, is in the gift of the Royal Academy of Sciences of Turin, and will be awarded to the scientific investigator, Italian or foreign, who within the period of four years from January 1, 1899, to December 31, 1902, shall be considered to have published the most noteworthy work on any of the physical sciences, taking that term in its widest sense.

One of the Nobel Prizes is awarded by the Carolinian Institute in Stockholm to the person who has been adjudged to have made the most important discovery in physiology or medicine during the preceding year. Recently two prizes, each of the value of about 11,000*l.* sterling, have been awarded by the Nobel Institute, one to Prof. Finsen, the founder of the Medical Light Institute at Copenhagen, and the other to Prof. Pawlow, of St. Petersburg, for his researches in regard to nutrition.

About thirty open prizes are offered each year by the Académie de Médecine of Paris, of which the most valuable is the François-Joseph Audiffred Prize. This is of the value of 1,000*l.*, and is offered to any person, without distinction of nationality or profession, who in the opinion of the Académie de Médecine is rightly adjudged to have discovered a preventive or cure of tuberculosis. The following are also among the more important offered for the year ending with the end of February, 1902; the sum specified in each case does not necessarily go to one candidate, but may be divided. The Academy Prize, awarded annually, worth about 40*l.*, is this year for a research on the *rôle* of toxins in pathology; the Baillarger Prize, of about 80*l.* (biennial), is for the best work on the treatment of mental diseases and the organisation of asylums; and the Charles Boullard Prize, also biennial, of 50*l.*, is for a similar subject. The Barbier Prize, of 80*l.* (biennial), is for the discovery of a cure for such "incurable" maladies as hydrophobia, cancer, epilepsy, typhoid and cholera. The Mathieu Bourceret Prize, of 50*l.* (annual), is for work on the circulation of the blood. The Campbell Dupierris Prize (biennial), of the value of 96*l.*, is for the best work on anæsthesia or the diseases of the urinary passages. The Chevillon Prize (annual), of 65*l.*, is for the best work on the treatment of cancer. The Desportes Prize, of 55*l.* (annual), will be awarded for the best work on practical medical therapeutics. The Herpin (of Metz) Prize (quadrennial), of 50*l.*, is offered for a research on the abortive treatment of tetanus. The Theodore Herpin (of Geneva) Prize, of 125*l.* (annual), is for a research on epilepsy and nervous diseases. The Laborie Prize, of 210*l.* (annual), is given for the greatest advancement in surgical science during the year. The Lefèvre Prize (triennial), of 75*l.*, is for a research on melancholia. The Meynot Prize (annual), of 108*l.*, is for the best work on ear disease; and the Saintour Prize (biennial), of 166*l.*, for the best work on any subject in medicine.

CHEMISTRY AT THE BRITISH ASSOCIATION.

In spite of the fact that a number of papers of general interest were contributed to Section B at the Glasgow meeting, the attendance was not so good as at the Bradford meeting last year. After the reading of the presidential address, a paper was read on duty-free alcohol by Dr. W. T. Lawrence, in which it was advocated that the Government should permit the use of non-methylated alcohol which had not paid duty for scientific purposes. In the course of the ensuing discussion, Dr. T. E. Thorpe drew attention to some of the difficulties with which the Excise Department would have to cope if such a course were permitted, and Prof. A. Michael, of Boston, stated that the United States Government allowed the use of non-methylated duty-free alcohol for scientific purposes and did not seem to meet with administrative difficulties. Dr. A. G. Green presented a comprehensive statistical report on the coal-tar industry, in which the progress made in this industry in Germany during recent years was strongly contrasted with its decadence in this country. The report of the Committee on preparing a new series of wave-length tables of the spectra of the elements was presented. Prof. Adrian Brown contributed a paper on enzymic action, in which he quoted the experimental results of an investigation of the action of invertase on cane sugar ; these results confirm the conclusion of previous workers that the action of inversion does not follow the simple law of mass action, but the author does not regard the action as independent of mass influence. He considers that the influence of mass in inversion changes is restricted by some other and hitherto unrecognised influence, and this he believes he has found in the time factor of molecular change. In reply to remarks by Prof. Reynolds Green, the author stated that his results were not necessarily in disaccord with those of Croft Hill. A paper was read by Prof. E. A. Letts and Mr. R. F. Blake, on the chemical and biological changes occurring during the treatment of sewage by the so-called bacteria beds. A large portion of the unoxidised nitrogen present in sewage disappears during the passage of the sewage through the so-called bacteria beds, and the authors consider that this may be due either to escape of the nitrogen in the gaseous state as free nitrogen or possibly as oxides or to the passage of the nitrogen into the tissues of animals or vegetables; both of these causes of loss may operate at the same time. An examination of sewage matter before and after passage through the beds showed that in nearly all cases the amount of dissolved nitrogen present in the sewage was greater after treatment than before, although, of course, if free nitrogen were evolved, only a minute fraction of it would remain dissolved in the sewage effluent. With respect to the possible biological explanation of the loss, it is pointed out that the sewage beds at Belfast and other places swarm with minute insects (*Podura aquatica*), and that species of worms are also present ; these in feeding on the sewage undoubtedly cause a loss of nitrogen. A paper was then read by Dr. S. Rideal on humus and the so-called irreducible residue in bacterial treatment of sewage, in which the results were detailed of a number of analyses of the humus-like substance or so-called irreducible residue produced in bacterial sewage beds. It is shown that in this material the ratio of carbon to nitrogen and the percentage of nitrogen in the organic matter present are very nearly the same as in humus mould ; the conclusion is drawn that if sewage has undergone proper bacterial fermentation the small quantity of peaty deposit formed is of the nature of humus and is practically inoffensive. In a paper on sulphuric acid as a typhoid disinfectant, Dr. S. Rideal advocated the use of sulphuric acid, either as such or in a more portable form as sodium bisulphate, for destroying the *Bacillus typhosus* in potable waters or in drainage from isolation hospitals. Mr. W. Ackroyd gave a paper on the inverse ratio of chlorine to rainfall, in which it was shown that when the observation periods are shortened to daily estimations of the chlorine, minimal amounts of rainfall are marked by maximum contents of chlorine, and *vice versâ*. In a second paper, Mr. Ackroyd dealt with the distribution of chlorine in Yorkshire. Mr. G. T. Beilby, in a paper on the minute structure of metals, showed that the microscopic examination of metallic surfaces has revealed that metals occur in two forms, viz., as minute scales or "spicules" (*a*) and as a transparent glass-like substance (*b*). The spicules do not vary much in size in the different metals and have a diameter of 1/300 to 1/400 of a millimetre ; the form *a* passes into the form *b* when the metal is pressed or hammered, and all polished metallic surfaces are covered with a thin layer of this transparent form as with a lacquer or enamel. Prof. G. G. Henderson and Mr. G. T. Beilby read a paper on the action of ammonia on metals at high temperatures ; on exposing platinum, copper, gold, silver, iron, nickel and cobalt to ammonia gas at 600° to 900° disintegration of the metal occurs, whilst a large proportion of the ammonia is decomposed into its elements. After the treatment the metal shows a spongy or cellular structure, as if it had been rapidly cooled whilst in a state of effervescence ; copper and iron rods of a quarter of an inch diameter are penetrated to the centre by the ammonia gas within half an hour, and copper exposed to the action of ammonia gas for seven days at 800° falls to a fine powder. Dr. W. C. Anderson and Mr. G. Lean gave a paper on aluminium-tin alloys, in which they show that these alloys evolve hydrogen freely when placed in water ; the microscopic examination of the water-corroded plates of alloy indicates that contact action between the excess of tin and the aluminium-tin compound is responsible for the spontaneous oxidation. Prof. Willy Marckwald, of Berlin, gave a very interesting demonstration and description of the properties of radium ; he had surmised, from the work of P. and S. Curie, that the barium salt extracted from pitchblende contains the radium salt as an isomorphous constituent, and that the process used by these workers for separating a strongly radio-active salt from the barium compound is probably similar to that in use for isolating the constituents of an isomorphous mixture. He therefore fractionally crystallised the barium chloride prepared from pitchblende from water, and found that pure barium chloride first separates and then a material, probably the eutectic mixture, which is very rich in the radio-active component. The most strongly radio-active fractions have the power of immediately discharging a charged gold leaf electroscope when at the distance of half a metre from the latter and when preserved under colourless glass soon turn it a deep brown colour. The radio-active substance is strongly luminescent in a dark room, and on interposing the hand between the preparation and a barium platino-cyanide screen, the bones in the fingers are seen sharply delineated on the screen. Prof. Marckwald also exhibited several preparations of so-called "phototropic" substances, compounds which change colour on exposure to sunlight and recover their original tint on preservation in a dark place ; he mentioned that the rapidity of change in either direction is considerably influenced by the temperature. Prof. A. Michael, of Boston, read papers on the genesis of matter and on the process of substitution ; he also contributed a paper on the three stereoisomeric cinnamic acids, in which he claimed to have proved that these three isomerides actually exist, that is, that one more isomeride exists than can be accounted for by the van 't Hoff hypothesis as interpreted by Wislicenus. Prof. G. G. Henderson and Mr. Corstorphine read a paper on the condensation of benzil with dibenzylketone ; in this condensation a tetraphenylcyclopentenolone is produced, and on heating it with red phosphorus and hydriodic acid a mixture of tetraphenylcyclopentene and tetraphenylcyclopentane is formed. Dr. Hodgkinson and Mr. L. Limpach contributed a paper on some relations between physical constants and constitution in benzenoid amines, and Dr. G. Young gave a paper on the existence of certain semicarbazides in more than one modification. Prof. W. H. Perkin, jun., gave a brief outline of his work on the synthetical formation of bridged rings. Prof. Joji Sakurai, of Tokio, in a paper on some points in chemical education, observed that in spite of the rapid progress made in chemistry during the past fifteen years, chemical education seemed still to be carried out in an inefficient and unsatisfactory manner. He pleaded for the more extensive use of physical chemistry as an educational agent, but wished to replace the ordinary name of this branch of the subject by the more rational one of general chemistry. Mr. W. Thomson contributed a paper on the detection and estimation of arsenic in beer and articles of food ; after noting that arsenic is introduced into barley during the process of malting owing to the employment of anthracite coal or coke containing arsenic, he suggested that all beers in 50 c.c. of which arsenic could be detected by any test whatever should be condemned. In a report entitled "The Equilibrium Law as Applied to Salt Separation and to the Formation of Oceanic Salt Deposits," Dr. E. F. Armstrong gave an excellent *résumé* of the work of van 't Hoff and his pupils on the investigation of the conditions attending the formation of the German deposits of magnesium salts ; the report was illustrated by the aid of a number of models. Dr. J. Gibson, in a paper on the electrolytic conductivity of halogen acid solutions, detailed the results of experiments which showed that halogen acid solutions of concentrations corresponding to a change of curvature of the electrolytic conductivity curve have altogether peculiar properties. Other papers were read by Mr. P. J. Hartog, on the flame coloration and spectrum of the nickel compounds, by Dr. Farmer, on the methods of determining the hydrolytic dissociation of salts, and by Dr. T. S. Patterson, on the influence of solvents on the rotation of optically active compounds.

ENGINEERING AT THE BRITISH ASSOCIATION.

SECTION G suffered badly at Glasgow, both in attendance and in the quality of the papers presented to it, from the Engineering Congress which was held in the University buildings during the preceding week ; many regular members of the Section were absent, and several valuable papers which would under ordinary circumstances have come to the Section were read instead at one or other of the Congress sectional meetings. On the opening day, after the presidential address, since the engineering departments of the Glasgow International Exhibition would naturally be frequently visited by members of the Section, it was arranged to have a paper descriptive of the mechanical exhibits; this was given by Mr. D. H. Morton, and proved most useful in assisting visitors to spend to the best advantage the hours they gave up to the Exhibition. The author, rightly enough, deplored the almost complete absence of any marine engineering exhibits and the poor show of locomotives; but he pointed out that in another of the great industries of Glasgow, steel making, there was a remarkably complete and most instructive series of exhibits, the enormous steel plates and huge steel forgings and castings being especially interesting. On the same day two interesting papers by Mr. J. R. Wigham, on a long-continuous-burning petroleum lamp for beacons and buoys, and on a new scintillating lighthouse light, were also read. In the first paper the author claimed that by burning petroleum and using the wick horizontally, so that the flame sprang from the side and not from the edge or ends, a steady light could be secured requiring no attention for a month; the slow continuous movement of the wick over the roller was secured by an ingenious arrangement in which the gradual escape of oil from a cylinder caused a float attached to the wick end to slowly descend, thus causing the wick to travel over the roller and so present a new surface to the flame. Examples of both these appliances were on show in the University buildings.

Another paper on this day was a short note by Mr. J. E. Petavel, in which he described a recording manometer he had devised, for obtaining a record of the high pressures reached by exploding charges of gas in closed cylinders. The instrument seemed well adapted for its purpose and ought to prove useful in gas and petroleum engine work.

Two reports were presented to the Section, one by the Small Screw Gauge Committee, in which the extreme trouble they had met with in obtaining accurate gauges was again described; and as a result practically little progress had been made since the last report was presented at Bradford; the other by the Committee on Resistance of Road Vehicles to Traction. This committee, which was appointed at Bradford, has discovered that the task it has embarked upon is a most difficult one, and one which will involve an expenditure far beyond any grants which could be given by the Association. The committee therefore sought and obtained authority to approach other bodies for financial help—many promises of substantial assistance had been given before the meeting. The work done up to date is briefly as follows:—(*a*) a dynamometer has been designed and is in course of construction; (*b*) a motor (lent by a member of the committee) is being fitted up to carry the dynamometer and is having a new and more powerful engine fitted to it; (*c*) it has been decided after careful consideration to begin the experiments by testing single wheels with various types of tyres, on artificial tracks, and then later on, with the experience gained in these preliminary investigations, the work on actual vehicles on ordinary roads will probably be much simplified. As some misapprehension exists as to the work the committee are attempting to carry out, it may be as well to state that it is work of the utmost value to the country, and work of a highly scientific character. No recent experiments have been carried out on this most important question, and designers of motor vehicles are obliged either to adopt rule of thumb methods or to fall back on data obtained by experiments made many years ago, on roads of quite different construction to those now in use, and with only one type of tyre, the solid steel or iron one. Should the committee succeed in the elaborate series of experiments they have planned, not only will designers of self-propelled vehicles have constants and data available for their use, upon which they can place absolute reliance, but road engineers will have exact information on two questions of the greatest interest to them, the effect of the method of moving a vehicle (that is, whether hauled of self-propelled) upon the life of a road, and secondly, the relative advantages of the different materials now in use for road making in regard to the frictional resistances encountered by the vehicles moving over them.

As the president of the Section devoted a part of his address to the modern development of passenger and goods traffic, it was natural that many of the papers read before the Section should deal directly or indirectly with this subject. Mr. N. D. Macdonald, in a paper on railway rolling stock present and future, attacked in vigorous fashion railway management in this country; he undoubtedly put his finger on many weak spots, notably as regards brakes and our old-fashioned goods trucks, but, like most amateurs when dealing with professional subjects, he spoilt much of his case by exaggeration. Professional engineers, like every other class of men, are liable to errors. They are prone to prefer old-fashioned methods and are too little inclined to take up and try novelties, but, after all, they are men of understanding and business men, and they are not likely to shut their eyes to improvements going on in other countries or to refuse to adopt them simply because foreigners first tried them. No one who travels much can fail to note the great improvements in railway management in this country during the past ten years, or the many changes still to be made if we are to keep abreast of the latest advances; but, after all, it is wiser to adopt radical changes cautiously, and we fancy the public will continue to place more reliance on the judgment of the trained expert than of the over-eager amateur.

Mr. Bunau-Varilla, formerly engineer-in-chief of the Panama Canal, in a paper on the canal, vigorously defended the judgment of those who selected that site for the canal instead of the Nicaragua route. The author gave many strong reasons for his preference for Panama; in particular he contrasted the almost entire freedom of the Panama site from seismic disturbances with the constant and ever-present danger to all concrete and masonry work all along the Nicaragua route from such causes. The case for Panama was so strongly put that it was unfortunate there was no real discussion on the paper, and therefore the arguments in favour of Nicaragua were not given a chance.

In electrical engineering, only two papers of much interest were presented, a valuable one by Prof. E. Wilson, on the commercial importance of aluminium, and a paper by Mr. Killingworth Hedges, on the protection of buildings from lightning. Prof. Wilson, after a brief description of the latest methods of manufacture, devoted himself mainly to an account of the use of aluminium as a conductor of electricity and its advantages for this purpose. In the discussion, the president (Colonel Crompton) referred to the great difficulty in securing uniform quality in aluminium tubes and sheets, and suggested that this stumbling-block must be removed if the extended uses of the metal which engineers hoped for were to become possible. Mr. K. Hedges drew attention to the work of the committee of British architects which was now engaged in considering the question of the protection of buildings from lightning effects, and to the urgent need of the adoption of some uniform system. He described in detail his re-arrangement of the system in use at St. Paul's Cathedral in London, where the conductors put up in 1872 were found to be quite useless for the purpose they were intended to serve. He had increased the number of ordinary conductors from air to earth, and, in addition, ran horizontal cables on the ridges of the roofs and in other prominent positions, thus encircling the building. These were connected to the vertical conductors wherever they crossed, and were also furnished at intervals with aigrettes or spikes, invisible from the ground level, thus giving many points of discharge. The author drew attention to the unsuitability of soldered joints for conductors, and described his own special joint box; he also explained the tubular earth he designed to get over the difficulties brought about by the old foundations of the cathedral interfering with the use of an ordinary earth plate. In the more purely mechanical side of its work, the Section dealt with two papers of much interest. Prof. George Forbes described his "folding rangefinder for infantry," and Mr. M. Barr the machines he had designed for the manufacture of type. Prof. Forbes' instrument is of the class known as "one-man portable-base range-finders," and possesses great accuracy up to a range of 3000 yards. It was founded on Adie's original instrument. It consists of a folding aluminium base of square tube, hinged at the centre, and a field glass. At each end of the base when opened out is a doubly reflecting prism, the rays of light from any object are reflected at each of these end prisms along each half tube, and then again at the centre into the two telescopes of the binocular glass, the final directions of the rays being parallel to the original. The angle between these rays is measured by means of two vertical wires, one in each telescope, one wire is fixed, and the other can be moved by a micrometer screw until the two appear to coincide and the object appears distinctly; the distance of the object is then at once given, to within 2 per cent. in 3000 yards. The author claimed great accuracy in stereoscopic vision, but Profs. Barr and Stroud, who took part in the discussion, and drew attention to the somewhat different lines on which they had worked in their range-finder (of which 400 are now in use in our Navy), differed on this point from him and preferred the method of single coincidence. Mr. Barr's paper, illustrated by lantern slides, was of too highly a technical nature to be dealt with in detail in the space at our disposal, suffice it to say it bids fair to revolutionise the method of carving or engraving the matrices used in type casting. The new process dispenses with wax and electro-plating processes, and secures a pattern cut out of solid brass in a much shorter time than was possible in any of the older methods. The author described the great difficulties he had met with in this work, both in the design of a strong, rigid and easily worked pantograph and in the attempt to carve out rapidly the large amount of superfluous material in the brass plate which had to be removed in order that the design should be left clearly in relief on a smooth plane; all these had now been overcome. Special machinery had been designed capable of extraordinary accuracy for cutting rapidly the punches needed, and for grinding the cutters.

The last paper we need refer to was one by Mr. C. R. Garrard on some recent developments in chain driving, which elicited a very interesting discussion, one of the best during the meeting. He gave figures as to the extraordinary pressure per square inch used in chain bearings as compared with those adopted in ordinary engineering work; in an ordinary bicycle chain as high a figure as 11,765 pounds per square inch may be occasionally reached; an account was given of the most recent methods of making these chains and of the quality of steel used, and, lastly, of the use of chains for high-speed driving purposes.

Apparently for the reason given before, local engineers took but little interest or share in the proceedings of the Section, and on the whole it was a disappointing meeting, both from the point of view of attendance and discussion on the papers and also in the quality and general value of the papers dealt with. Section G still calls in vain for papers from the numerous engineering laboratories throughout the kingdom; there are scores of young engineers, engaged in scientific research work, and until they can be got hold of, and the class of papers radically altered, Section G will fail to appeal to the great body of engineers in the country. T. H. B.

ANTHROPOLOGY AT THE BRITISH ASSOCIATION.

THE Anthropological Section of the British Association met in the new Anatomy Department of the Glasgow University, which was formally opened by Lord Lister on the first afternoon of the meeting. The address of the president of the Section, Prof. D. J. Cunningham, F.R.S., dealt with the human brain, and the part which it has played in the evolution of man, and is to be found in full in NATURE of September 26, p. 539. The rest of the programme was planned as follows: Thursday morning and Monday afternoon were devoted to physical anthropology, which was represented by an unusual number of highly specialist papers; Tuesday to ethnography, chiefly American and Malayan; Friday and Monday morning to archæology; and Wednesday to anthropometry and folklore. The principal papers are classified below in order of their subject-matter.

Anthropography.

Prof. J. Cleland, F.R.S., gave a demonstration of the cartilage of the external ear in the monotremata in relation to the human ear, illustrated from *Echidna* and *Ornithorhynchus.*

Dr. J. F. Gemmill illustrated, by a series of fine microscope-projections, the origin of the cartilage of the *stapes* and its continuity with the hyoid arch, showing that the *stapes* is developed independently of the periotic capsule, and belongs to the hyoid bar.

Prof. A. Macalister, F.R.S., contributed notes on the morphology of transverse vertebral processes, with the object of determining embryologically the morphological relations of the several parts of the neural arch. A further note on the third occipital condyle showed that two distinct structures are comprised under this name—a mesial ossification in the sheath of the notochord, and a lateral and usually paired process caused by the deficiency of the mesial part of the hypochordal element of the hindmost occipital vertebra, with thickening of the lateral portion of the arch.

Principal Mackay read a paper on suprasternal bones in the human subject, which gave rise to an animated discussion of the embryological evidence.

Prof. J. Symington combated Hochstetter's view that the "temporary fissures" of the human cerebral hemispheres are merely the product of incipient maceration and putrefaction in laboratory specimens. He admitted, however, that the arcuate fissure is of no morphological significance, and that it has nothing to do with the hippocampal fissure, which latter can be traced in the fœtal brain in the position which it occupies throughout life in the monotremata and marsupialia. The rudimentary grey and white matter on the back of the adult human *corpus callosum* is probably the remains of a hippocampal formation.

Mr. J. F. Tocher and Mr. J. Gray discussed the frequency and pigmentation value of the surnames of Scottish school-children in East Aberdeenshire. There is a presumption that the present possessors of surnames inherit some of the physical characteristics of their ancestors of the thirteenth and fourteenth centuries, when hereditary surnames first became common in Scotland, and this is confirmed by the fact that among 751 surnames noted, 63 Highland names covered 13 to 14 per cent. of the population; the same proportion of Highland blood as had been previously ascertained by measurements. There is wide variability in the pigmentation value of different surnames; Frasers, for example (from blonde Inverness-shire), tending to be blonde; and Robertsons and Gordons (from Perthshire and West Aberdeenshire) to be dark. A committee of the Association was appointed to assist Messrs. Gray and Tocher in organising a similar pigmentation-survey for the school-children of the rest of Scotland.

Miss Nina Layard exhibited a skull found in peat in the bed of the river Orwell, now in the museum of the College of Surgeons. It proved to be of the same pre-Roman British type which is common in the Fen district.

Mr. W. M. Douglas, superintendent of police, described the working of the Bertillon method of personal identification, as practised in Glasgow. In discussion, Dr. Garson laid stress on the value of the form of nose and ear in identification, as against the colour of hair and eye; pronouncing photographs useless, but finger prints most important.

Ethnography.

The Report of the Ethnographic Survey of Canada summarised the work of the year, and introduced a copious memorandum by Mr. C. Hill Tout on the natives of British Columbia. The committee was reappointed with a grant of 15*l*. Mr. J. O. Brant Sero, a Canadian Mohawk, gave an account of the traditional history of the Caniengahakas and their culture-hero Dekanawideh, with notes on their social and political organisation. This striking communication is printed in full in *Man* for November.

Mr. Hesketh Prichard described in detail the manners and customs of the Tehuelche Indians of Patagonia, and Mr. Seymour Hawtrey those of the Lengua Indians of the Gran Chaco.

The Report of the Skeat Expedition to the Malay Peninsula contained an elaborate account of Malay industries, and was illustrated by photographs and reproductions of native implements and fabrics. Mr. Skeat contributed a detailed study of the Sakais and Samangs, wild tribes in the interior of the Peninsula who retain many marks of a primitive stage of culture.

Messrs. Annandale and Robinson, who are still in the field, sent a full account of the half-Siamese half-Malay community of Sai-Kau in the northerly border-state of Nawnchik, in which the two peoples live side by side and have given rise to a mixed type of culture. Physical measurements show the survival in both of a marked Negrito element.

Mr. R. Shelford propounded a provisional classification of the swords of the tribes of Sarawak.

Dr. W. H. R. Rivers discussed the functions of the maternal-uncle, son-in-law and brother-in-law in Torres Straits, with the view of illustrating the underlying principles and the practical working of certain phases of primitive society.

Mr. C. S. Myers analysed the emotional life of the inhabitants of Murray Island, which he studied in the course of the Cambridge expedition to Torres Strait. The excitability of the native is due rather to the varying sanctions of society than to distinctive mental constitution.

Mr. W. Crooke described the organisation of the projected Ethnographic Survey of India and offered criticisms in detail, regretting, in particular, that it had not been found possible to provide for systematic photography of native types, occupations and ceremonies.

Mr. R. A. S. Macalister gave an account of the customs, ceremonies and beliefs of the Fellahin of Western Palestine.

Mr. D. MacRitchie, under the title "Hints of Evolution in Tradition," discussed the value of the widespread stories of giants, dwarfs, fairies and hairy folk as evidence of the survival of primitive types of mankind in remote localities until comparatively recent times.

Mr. J. S. Stuart Glennie criticised Dr. Frazer's views of the relations between magic, religion and science, as expressed in the second edition of the "Golden Bough." The new stage which Dr. Frazer named "science" would give a higher and more verifiable form to the common ideal and social observances which constituted religion.

Archaeology.

Dr. W. Allen Sturge opened a discussion on the chronology of the Stone Age of man, with especial reference to his coexistence with an Ice Age, laying stress on the evidence of patination as a test of relative age, and exhibiting a series of implements which appeared to show traces of reworking after a prolonged interval, and also scratches on a patinated surface, which he claimed to be due to ice-movement. In discussion, Sir John Evans pointed out that patination is not always a safe guide as to relative age; and Prof. Kendal and others held that scratches similar to those exhibited are produced by small local movements in the mass of a gravel-bed.

Mr. Coffey attacked the same question from another side by an exhibit of naturally chipped flints from the Larne gravels and North Irish beaches, which so closely resembled the chipping of the alleged "Eolithic" implements as to prevent any certain conclusion being reached as to what really is artificial chipping.

Miss Layard exhibited a flint palæolith with alleged "thong-marks," which seemed, however, to be patches of the rough skin of the nodule; and also a series of implements of stone and horn from the neighbourhood of Ipswich.

Mr. F. D. Longe exhibited a piece of yew from the forest bed near Kessingland, showing cuts made by a straight-edged instrument. Doubts were, however, expressed as to the antiquity of the cuts.

The Report on the age of stone circles gave full particulars of excavations conducted by the committee at Arbor Low. The occurrence of a Bronze Age interment-barrow *on* the rampart of the circle gave a downward limit of date for the latter, and the discovery of flint flakes and other objects *in situ* went far to determine an upward limit. Further investigation, however, is required, and the committee was reappointed with a grant of 30*l*.

An important paper on excavations on Neolithic sites in the Isle of Arran was contributed by Drs. Duncan and Bryce. The results show that the mere presence of stone implements affords no test of the archæological horizon, but that the pottery found in the "Megalithic cists serially arranged" distinguishes these as earlier than the short cists in cairns or circles, and as truly Neolithic. No traces of cremation were found; but only a few of the human remains were in a condition for examination. The cephalic indices of four individuals were 66·6, 70, 75, 75·5, and the anatomical characters were identical with those of the English "long-barrow" folk. The paper will be published in full in *Proc.* Soc. Antiq. Scot., and the anthropographic material in *Journ.* Anthr. Inst.

Dr. Munro gave an account of a "kitchen midden" excavated near Elie, in Fife, which was proved to occupy the site of a wooden house belonging to pastoral or hunting people, and to belong to the eighth century, A.D. (cf. *Proc.* Soc. Antiq. Scot. xxxiv.)

Mr. J. H. Cunningham described the excavation by the Scottish Society of Antiquaries of the Roman station at Ardoch in Perthshire; the results are published fully in *Proc.* Soc. Antiq. Scot., xxxii. Mr. Thomas Ross described the recent excavation of the Roman camp at Inchtuthill.

The Report of the Silchester Excavation Committee recorded the clearance of four fresh *insulae* (xxiii–xxvi) and the discovery of some interesting pavements, and of a large hoard of smith's tools. The Committee was reappointed with a grant of 5*l*. and a similar committee was granted to cooperate with the Cardiff Naturalists' Club in excavation at Gelligaer.

Mr. R. A. S. Macalister discussed the external evidence bearing on the age of Ogham writing in Ireland, pointing out that certain Ogham inscriptions occur in association with tumuli, circles, and alignments, on stones with non-Christian symbolism, or in other circumstances which suggest a pre-Christian origin for the Ogham script.

Mr. James Paton gave a demonstration of Scottish antiquities in the Art Gallery of the Glasgow Exhibition; an innovation which was fully justified by the result, and might be repeated elsewhere with advantage.

Mr. C. S. Myers described the bones of Hen Nekht, an Egyptian king of the third dynasty, who was of giant stature (1870 mm.), and identified him with the gigantic king recorded diversely by Manetho as penultimate king of the second dynasty, and by Eratosthenes as first king of the third.

The Report of the Cretan Exploration Committee summarised the results of excavation on Mycenæan sites at Knossos, Zakro and Præsos in the seasons 1900 and 1901. At Knossos the remains of a splendid palace have yielded a large number of fragmentary fresco paintings, many works of art in bronze, stone and pottery, and a great wealth of clay tablets inscribed in Ægean hieroglyphic and linear characters. The excavations at Knossos demand another season's work, and the Committee was reappointed, with a further grant of 100*l*.

Mr. A. J. Evans, F.R.S., supplemented the Report with a description of the Neolithic settlement which underlies the Mycenæan palace at Knossos, drawing particular attention to the stone mace heads and small human figures in clay and marble, which seemed to him to present Anatolian analogies, and to indicate intercommunication between the Ægean and Babylonia. The Neolithic culture of the Ægean presents points of strong contrast with that of the Bronze Age; and the absence as yet of spiraliform ornament confirms the opinion that this motive was introduced into the Ægean at a later date, and probably from Egypt.

Mr. Bosanquet gave a detailed account of the excavations on the site of Præsos, the ancient capital of eastern Crete. Two large sanctuaries were discovered, together with an "andreion" or public dining-hall, of Hellenistic date, and a remarkable inscription written in Greek characters of the fifth century, but composed in the Eteocretan language.

Mr. Hogarth contributed a description of a Mycenæan site excavated by him at Zakro on the east coast of Crete, with houses, tombs, much pottery of new types, and a deposit of clay impressions from Mycenæan seal-stones.

Mr. R. A. S. Macalister described the result of several seasons' excavation on small sites in western Palestine, which throw important light on the civilisation of the early Israelites and of Philistia.

Interim reports were received from the committees on anthropological photographs and on the present state of anthropological teaching. A new committee was appointed, with Prof. Macalister, F.R.S., as chairman, Mr. C. S. Myers as secretary, and a grant of 15*l*. to conduct anthropometric observations among the native troops of the Egyptian army.

BOTANY AT THE BRITISH ASSOCIATION.

AFTER the delivery of the presidential address by Prof. Bayley Balfour, F.R.S., Dr. Lotsy (Hilbersum, near Arnhem, Holland) explained to the Section the aims and proposals of the International Association of Botanists, which was founded at Geneva in August. The Association has purchased the *Botanisches Centralblatt*, which it proposes to conduct as a first-class review of current botanical literature. Dr. Lotsy pointed out that an increased number of subscribers and shareholders is desired in order to ensure success. On Saturday the members of the Section were invited by the President to the Edinburgh Royal Botanic Garden, where they inspected the museum and garden and were afterwards entertained at lunch by Prof. and Mrs. Bayley Balfour. The excellence of the museum preparations was a striking feature, particularly the specimens and dissections preserved in spirit and labelled for teaching purposes. A very useful paper was read before the Section by Mr. Tagg, in which he gave an account of the methods employed by him with conspicuous success in the Edinburgh Museum in preserving and preparing plants for museum purposes.

On Friday afternoon Prof. Reynolds Green, F.R.S., delivered a lecture on flesh-eating plants. Monday morning was devoted to a joint discussion (Botanical and Educational

Sections) on the teaching of botany, an account of which has appeared in the report of the work of the latter Section. Mr. A. G. Tansley described the vegetation of Mount Ophir and gave a lantern exhibition of several photographs which he had taken during a recent expedition to the Malay Peninsula. The views of dense masses of *Matonia pectinata*, *Dipteris conjugata* and *D. Lobbiana* growing in the Mount Ophir region were particularly striking as illustrating the present home of these isolated fern genera which played a prominent part in European vegetation during the Mesozoic epoch. Some excellent botanical photographs from the Malay Peninsula were also exhibited by Mr. Yapp, who acted for some months as botanist to the Skeat Expedition.

Thallophyta.—Cytology of the Cyanophyceæ, by Harold Wager. The researches of Scott, Zacharias, and others have definitely revealed the fact that the contents of the cells of the Cyanophyceæ are differentiated into two distinct portions, an outer peripheral layer in which the colouring matters are placed, and a central colourless portion which is usually spoken of as the "central body." The central body is regarded by many observers, and notably by Bütschli, as a true nucleus. According to the author's observations, it appears to resemble the nuclei of higher organisms, in that it is composed of a chromatic network, but it differs from them in the absence of a nuclear membrane and nucleolus. Staining and other reactions show that chromatin is present, but in most cases only in small quantities. The presence of phosphorus in the central body can also be demonstrated, as Macallum has shown, by means of the molybdate phenylhydrazine reaction. In the process of division the cell begins to divide and new cell-walls are formed independently of the division of the nucleus. In the process of nuclear division the chromatin threads become drawn out longitudinally and parallel to one another, and are then divided transversely. Some of the division stages, especially in elongate cells, resemble stages in true karyokinetic division.

The Bromes and their brown rust, by Prof. Marshall Ward, F.R.S. The author has been for some time occupied with the grasses of the genus *Bromus* and the behaviour of the *Uredo* of the brown rust (*Puccinia dispersa*) upon them. The plan of the investigation includes the nature of infection and conditions of attack, and all discoverable relations between host and parasite. The germination of the grass seeds has led to interesting points. They can be treated antiseptically in various ways and grown as pure cultures in nutritive solutions in glass tubes of various shapes, designed either to allow of the continuous aëration of the plantlet by a current of filtered air drawn through by aspirators, or not.

Such pure cultures of the grass were then infected with uredo-spores, and in ten to twelve days gave rise to *pure cultures of the Uredo*, which germinated and infected other similarly pure cultures of the grass inoculated with them.

Long series of sowings were made to test the conditions of germination of the uredo-spores. The minima and maxima temperatures of germination were found to be about 10° C. and 27°·5 C. respectively, the optimum being about 18° C. The effects of light, of other organisms (*e.g.* Algæ), of various extracts, and of the age of spores, &c., were also examined. Infection experiments on pot plants were made—several hundreds in all—on twenty-one species or varieties of *Bromus*.

The general results are, put very shortly, as follows:—Although the *Uredo* examined is in all morphological respects absolutely identical on all the species of *Bromus* on which it occurs, nevertheless if spores gathered from *B. sterilis* are sown on *B. mollis* the infection fails, whereas spores of the same batch sown on *B. sterilis* infect normally and rapidly. And similarly in other cases. Spores from *B. mollis* readily infect *B. mollis*, and (less certainly) its allies *B. secalinus* and *B. velutinus*, *B. arvensis* and others of the *Serrafalcus* group; but they fail on *B. maximus*, *B. tectorum*, *B. sterilis*, *B. madritensis*, &c.—the *Stenobromus* group—and so with other cases.

These observations lend no support to either the mycoplasm theory of Eriksson, or to any theory which attempts to explain outbreaks of rust to intra-seminal infection handed down from parent to offspring, and the author believes that the difficulties hitherto met with in understanding the sudden epidemics of these rust-diseases will disappear as we gain exact information of the conditions of germination, infection, and incubation of the disease-producing parasite; as also of its habits of lurking in the older leaves of the grass in spots where the production of a very few spores—quite invisible on a casual overhauling of the grass—prepares the way for more extensive infection as the weather changes.

Prof. Marshall Ward, F.R.S., communicated a paper by Mr. T. Barker on spore-formation in yeasts, also an account, by Mr. Howard, of a *Diplodia* parasitic on cacao and on the sugar-cane.

Pteridophyta.—Contributions to our knowledge of the gametophyte in the Ophioglossales and Lycopodiales, by William H. Lang. (1) The prothalli of *Ophioglossum pendulum* and *Helminthostachys zeylanica*. The wholly saprophytic prothallus o *O. pendulum* is at first button-shaped, but by branching the older prothalli come to consist of a number of short cylindrical branches radiating into the humus. The young prothallus and the branches are radially symmetrical. In the older parts all the cells except the superficial layers contain an endophytic fungus. The prothallus is monœcious. The antheridia are sunken, with a slightly convex outer wall one layer of cells thick; in surface view this shows a triangular opercular cell. The neck of the archegonium, which projects very slightly, consists of about sixteen cells in four rows. The central series in all archegonia yet observed consists of an ovum and a single canal cell. A basal cell is present. The prothalli of *Helminthostachys* were found a few inches below the surface of the soil in a frequently flooded jungle in Ceylon. The prothalli are radially symmetrical. The smallest were stout cylindrical structures the lower part of which was darker in tint and bore rhizoids; the upper bore the sexual organs, which arise acropetally behind the conical apical region. In prothalli which bear archegonia the vegetative region is relatively more developed, and in both these and the male prothalli it becomes more or less lobed. The antheridia are large and sunken; the slightly convex outer wall is two-layered except at the places where dehiscence may occur, which consist of single large cells. The archegonia have a neck, consisting of four rows of cells, which projects considerably.

(2) On the mode of occurrence of the prothallus of *Lycopodium selago* at Clova. The sporophyte of this plant is very common on moors, screes and crags in the Clova valley, and in these situations it seems to be reproduced almost entirely by means of bulbils. On the sometimes submerged margin of Loch Brandy, however, numerous sexually produced plants and prothalli may be found growing in the soil between the stones. The difference in the conditions under which the sporophyte can exist and those necessary for the successful germination of the spores is analogous to what has been found to be the case for *Helminthostachys*.

(3) On some large prothalli of *Lycopodium cernuum*. The prothalli of this plant, described by Treub, were of small size, one of the largest measuring 2 mm. in height by 1 mm. across. On the banks of roads close to Kuala Lumpur much larger prothalli were found. They were cake-like structures, of a deep velvety green colour, about 2 mm. in vertical thickness, but measuring sometimes 6 mm. across: they were attached to the soil by numerous rhizoids springing from the flat base.

(4) On the prothallus of *Psilotum*. The prothallus of this plant was searched for without success in Ceylon. The sporophyte occurred on tree-fern trunks on Maxwell's Hill in Perak, and a single prothallus was found there embedded among the roots of a tree-fern close to a *Psilotum* plant. No other plants grew on this tree-fern, and, although a few species of *Lycopodium* occur sparingly in the locality, there seems a strong probability in favour of this specimen being the prothallus of *Psilotum*. The specimen measured one quarter of an inch in height by $\frac{3}{16}$ inch across at the widest part. It consists of a cylindrical lower region covered with rhizoids; near the lower end of this is a well-marked conical projection (primary tubercle). The upper part widens out suddenly, and its thick overhanging margin bears numerous antheridia. In general form the prothallus resembles some small specimens of *Lycopodium cernuum*, but the upper region, from which assimilating lobes are absent, finds its closest analogue in prothalli of *L. clavatum*.

Some observations upon the vascular anatomy of the Cyatheaceæ, by D. T. Gwynne-Vaughan. In a number of Dicksonias with creeping or prostrate stems the vascular system is solenostelic, the leaf-traces departing as a single strand curved into the form of a horse-shoe, with its concavity facing towards the median line of the rhizome—*Dicksonia adiantoides*, *cicutaria*, *davallioides*, *apiifolia*, and *punctiloba*. In *Dicksonia rubiginosa* the vascular ring is interrupted by gaps other than those due to the leaf-traces, and it may therefore be termed polystelic. In addition, there are two or three small accessory steles lying within the vascular ring. Throughout the internode the course of these internal steles is quite free from the vascular ring, but at each node one of them approaches the free margin of the leaf-gap, and completely fuses with it, separating off again after the leaf-gap has become filled up. *Pteris elata* var. *Karsteniana* has a typically solenostelic vascular ring, and also possesses internal accessory steles, which behave like those of *Dicksonia rubiginosa*, but they are relatively larger, and frequently they all fuse up together so as to form a second, inner, completely closed vascular ring. It is suggested that the several internal steles and vascular rings that occur in the Saccolomas and in *Matonia pectinata* are also of the same origin and nature as those described by the author.

Prof. Bower, F.R.S., exhibited a specimen of *Ophioglossum simplex*, n. sp., collected by Mr. Ridley in Sumatra. It appears to be entirely without the sterile leaf-lobe, though the fertile spike is characteristically that of an *Ophioglossum*. If it be actually demonstrated that the sterile lobe is really absent, this peculiar plant may give rise to considerable morphological discussion.

The anatomy of *Ceratopteris thalictroides*, by Sibille O. Ford. *Ceratopteris thalictroides* is the single member of the Parkeriaceæ. It is an annual aquatic fern which occurs in the tropics, either rooted in the mud or floating freely. The stem is much reduced; sterile as well as fertile leaves are found, both kinds bearing numerous vegetative buds. The sporangia are scattered on the under side of the fertile leaves, and have no true indusium. The roots in the mature plant arise from the bases of the petioles. An account was given of the anatomy of the leaves, roots and polystelic stem. The apex of the stem was described as having the form of a cone terminating in a three-sided cell. Miss Ford spoke of *Ceratopteris* as possessing more strongly marked affinities with the Polypodiaceæ than with any other of the leptosporangiate ferns, and as possibly intermediate in position between the Marsiliaceæ and Polypodiaceæ.

On two Malayan "myrmecophilous" ferns, by R. H. Yapp. *Polypodium* (*Lecanopteris*) *carnosum* and *Polypodium sinuosum* are two epiphytic ferns, which occur almost exclusively in the Malay Peninsula and Archipelago. Their creeping rhizomes are thick and fleshy, the ventral surface closely adhering to the substratum, the dorsal bearing the leaves, which are articulated upon large conical leaf-cushions. Branching is lateral, and is so frequent in the case of *Polypodium carnosum* that thick compact masses of interlacing stems are formed, which completely encircle the branches of the trees on which the fern grows. The fleshy stems of both ferns are traversed by an extensive system of hollow spaces, which are invariably inhabited by colonies of ants. These "ant-galleries" are arranged on a perfectly definite plan, the details of which differs to some extent in the two ferns. In both cases there is a single main ventral gallery, which runs in a longitudinal direction through the stem, giving off a lateral gallery to each branch and a dorsal one to each leaf-cushion. The galleries are formed by the breaking down of a large-celled, thin-walled tissue, which in the youngest parts of the stem appears to function as a water-reservoir. Though undoubtedly closely allied species, these ferns have been placed by many authorities in different genera.

Mr. George Brebner gave an account of the anatomy of *Danaea* and other Marattiaceæ. In *Danaea simplicifolia* the primary vascular axis is a simple concentric stele. The pericycle may be absent or only imperfectly represented. There is a definite endodermis, but it is not clear that the constituent cells are always the innermost ones of the extrastelar tissue. When the cotyledon-trace is about to be given off, the xylem of this vascular axis, or "protostele," is separated into more or less unequal portions by a layer of parenchyma. The parenchyma increases in amount, and ultimately the cotyledon-trace is separated from the central stele. The cotyledon-trace is collateral. The next few leaf-traces are given off in the same manner, and are also collateral. The stele resumes its simple "protostelic" appearance. As further leaf-traces depart from, and root-traces join, the vascular axis, the primitive structure is gradually modified, and it may become more or less crescentic, forming an incomplete, or even complete, gamostelic ring. The spaces left by the departure of the leaf-traces now constitute leaf-gaps. The vascular tissue of this stage may be described as a "siphonostele with leaf-gaps." In describing the stele of the Marattiaceæ, the author confirmed and extended Miss Shove's statement (*Annals Bot.*, 1900) as to the internal position of the protophlœm.

On the anatomy of *Todea*, with an account of the geological history of the Osmundaceæ, by A. C. Seward, F.R.S., and Miss S. O. Ford. In this paper the authors dealt with the anatomy of the stem of *Todea barbara*, which in the main agrees with that of *Osmunda regalis*, as described by Zanetti (*Bot. Zeitung*, 1895). The paper included an account of the origin of the leaf-traces, the anatomy of the "seedling" plants and a summary of the geological history of the Osmundaceæ.

Remarks upon the nature of the stele of *Equisetum*, by J. T. Gwynne-Vaughan. The vascular bundles of *Equisetum* are usually compared with those of a monostelic phanerogam, both in structural detail and with regard to their course into the leaf. Observations made upon the stems of *E. Telmateja*, &c., show that this comparison cannot be satisfactorily maintained.

The xylem of the so-called vascular bundle of *Equisetum* was described as consisting of three strands, two of which are lateral and cauline, while the median, or carinal, strand is common to both stem and leaf. The fact that only a small portion passes out as a leaf-trace, and not the bundle as a whole, constitutes an essential point of difference between it and the bundle of a phanerogam. Potonié has established a comparison between the secondary vascular tissues of the *Calamariae* and the *Sphenophyllaceae* by mentally doing away with the central mass of primary xylem that exists in the latter. By inverting this procedure, and considering it possible that the ancestors of the equisetums may have possessed a xylem that extended to the centre of the stem, one is led to derive their structure, as it exists at present, from the modification of a stele with a solid central mass of centripetal xylem, such as that of *Sphenophyllum*, or of certain Lepidodendreæ.

It is suggested that the lateral xylem strands in the vascular bundles of the existing equisetums may perhaps be taken to represent the last remnants of a primitive central mass, and that this would be entirely in agreement with their apparently centripetal development, and in particular with their cauline course.

Fossil Plants, &c.—On a primitive type of structure in Calamites, by D. H. Scott, F.R.S. Palæontological research has afforded evidence that the horsetails and lycopods had a common origin. The class sphenophyllales, restricted, so far as we know, to the Palæozoic epoch, combines in an unmistakable manner the characters of equisetales and lycopodiales, while at the same time presenting peculiar features of its own.

The synthetic nature of the sphenophyllales, indicated clearly enough in the type-genus *Sphenophyllum* itself, comes out still more obviously in the new genus *Cheirostrobus*. So far nothing has been found to bridge the gulf which separates the anatomy of the Calamarieæ (Palæozoic equisetales) from that of the sphenophyllales or the lycopods.

Dr. D. H. Scott gave an account of a calamite from the Calciferous Sandstone of Burntisland, in which each vascular bundle is characterised by the possession of a distinct arc of centripetal wood on the side towards the pith. The carinal canals are present, as in an ordinary calamite, and contain, as usual, the remains of the disorganised protoxylem. They do not, however, as in other equisetales, form the inner limit of the wood, but xylem of a considerable thickness, and consisting of typical tracheides, extends into the pith on the inner side of the canal, which is thus completely enclosed by the wood. That the organ was a stem, and not a root, is proved, not only by the presence of the carinal canals, but by the occurrence of nodes, at which the outgoing leaf-traces are clearly seen. This appears to be the first case of centripetal wood observed in a calamarian stem, and thus serves to furnish a new link between the Palæozoic equisetales and the sphenophyllales, and through them with the lycopods.

Provisionally, the new stem may bear the name of *Calamites pettycurensis*, from the locality where it occurs.

In a paper on the past history of the Yew in Great Britain and Ireland, Prof. Conwentz (Danzig) gave an account of his researches into the causes of the disappearance of this species from nearly all parts of middle and northern Europe. He expressed the view that the genus *Taxus*, which has now passed its zenith, is of no great geological antiquity; most of the Tertiary fossils described as species of yew were found to have been incorrectly determined. Prof. Conwentz dealt with a mass of evidence which he had examined, proving that the yew had been formerly widely distributed in regions where it has ceased to exist. The evidence was derived from the microscopical examination of subfossil wood, the occurrence of prehistoric and historic antiquities preserved in the British Museum, in the Science and Arts Museum in Dublin and elsewhere, and from the abundance of place-names in England, Scotland and Ireland which owed their origin to the former existence of yew trees.

On the distribution of certain forest trees in Scotland, as shown by the investigation of post-glacial deposits, by W. N. Niven. The author gave a summary of facts obtained from various topographical books and other sources concerning the distribution of the following trees:—Hawthorn, elder, common ash, birch, alder, hazel, oak, willow, yew and fir, all of which, with the exception of the ash, are considered natives of Scotland. The cones of the silver fir have been dug out of the peat in Orkney, but this tree is not now indigenous to Scotland. Several shrubs, including the juniper and raspberry, as well as many flowering plants, have also been discovered. Mr. Niven pointed out that there are few parts of Scotland, however treeless at the present day, that were not in remote, and even in comparatively recent, times covered with woodlands. This is also shown by the place-names.

The evidence, which is obtained by the examination of the various post-glacial deposits, indicates in a very clear manner that the trees recorded should be considered truly indigenous to Scotland.

Prof. Potonié, of Berlin, read a paper on "Die Silur- und Culm-Flora des Harzes." On certain points in the structure of the seeds *Aethiotesta*, Brongn. and *Stephanospermum*, Brongn., by Prof. F. W. Oliver. The author gave some account of the anatomy of the fossil gymnosperm seed named by Brongniart *Stephanospermum akenioides*, and of another seed nearly allied to the foregoing which he provisionally recognised as *Aethiotesta subglobosa*, Brongn. Attention was drawn to the mantle of tracheal tissue which invests the nucellus in both cases. The possible physiological significance of this tissue was considered, and some suggestions were offered as to the conditions which led to the evolution of the seed in this group. The author expressed the opinion that there was considerable probability that the seed habit was at its origin a xerophilous adaptation.

The structure and origin of jet, by A. C. Seward, F.R.S. The author has recently examined several sections of Yorkshire jet in the British Museum, which he believes demonstrate the origin of this substance from the alteration of coniferous wood and, in part at least, of wood of the Araucarian type. Sections cut from specimens, which consist in part of petrified wood and in part of jet, enable us to trace a gradual passage from well preserved Araucarian wood to pure jet, which affords little or no evidence of its ligneous origin. The conclusion arrived at is that the Whitby jet owes its origin to the alteration of coniferous wood. The fact that jet frequently occurs in the form of flattened blocks of wood in all probability admits of the natural explanation that the jet has been derived from the wood, the form of which it has assumed, and not that the jet was formed elsewhere and permeated the tissues of the wood as a fluid bitumen.

Mr. E. A. N. Arber described a number of specimens contained in the Clarke collection of fossil plants from New South Wales. The collection, which is now in the Geological Museum, Cambridge, is noteworthy as being one of the earliest (1839-44) obtained from the continent of Australia.

A chapter of plant evolution, by A. C. Seward, F.R.S. The author described the chief features in the floras ranging from the Rhætic to the Wealden; he drew attention to the dominant types which characterised this long succession of stages in the earth's history and discussed the progress of plant-evolution from the close of the Triassic period to the appearance of angiosperms in rocks of Lower Cretaceous age.

Morphology.—Cuticular structure of *Euphorbia Abdelkuri*, by Prof. Bayley Balfour, F.R.S. *Euphorbia Abdelkuri* is an interesting succulent plant which has been brought home from a small island in the vicinity of Sokotra by the Ogilvie-Forbes Expedition. The outer surface of the plant in the fresh condition appears to be covered with a crust which readily cracks off, and on examination this is found to consist of a number of prisms. At first sight these may be taken for some form of mineral incrustation, but they are not of this nature, being formed by the cuticle of the epidermal cells. This does not form an uninterrupted layer over the epidermis, but the cuticle of each cell is separable from that of the adjacent ones, and the prisms are merely blocks of cuticle, each one belonging to a single cell. This is a construction different from that which is ordinarily met with in plants with a thick cuticular layer.

Miss A. M. Clark described abnormal secondary thickening in *Kendrickia Walkeri*, a tropical epiphytic climbing shrub. The anatomy of the young stem is typical of the family Melastomaceæ. At an early stage numerous small patches and several large wedge-shaped areas of thin-walled unlignified wood-parenchyma are cut off from the inner side of the completely circular cambium ring. Tylosis is of frequent occurrence, and the tylosed cells may develop into sclerotic cells inside the vessels and racheids. At a later stage, the unlignified wood-parenchyma cells at the central margin of the wedge area take upon themselves new growth accompanied by cell-division. The product of this new growth proceeds to split the axial woody ring into a number of portions, with subsequent destruction of the identity of the wood elements. Later, the quiescent cambium lying between the original internal phloëm and the axial woody ring takes upon itself new growth, and proceeds to lay down xylem on the one side and phloëm on the other.

The histology of the sieve tubes of *Pinus*, by A. W. Hill.—The author's researches have proved that the results obtained by Russow are, in the main, correct; the mature sieve-plate is traversed by groups of callus rods, which are interrupted at the middle lamella by median nodules, and each callus rod contains from three to seven striæ—or spots if examined in surface-view—which are strings of slime. The youngest sieve-plates or pit-closing membranes, which could be examined, showed "connecting threads" like those in ordinary tissue; but in the so-called "boundary cells"—*i.e.* the youngest thick-walled sieve-tubes—a change takes place, namely, the appearance of the callus. Callus first appears on one surface of the sieve-plate, at the places where the groups of "connecting threads" occur, and it gradually spreads as a rod along a group of the threads to the middle lamella; a similar change then takes place on the other side of the lamella. The lamella itself, however, is not converted into callus, but a refractive median nodule appears separating the two portions of the callus rod. Accompanying this change the protoplasmic threads become converted into slime strings. The changes described were considered by the author to be due to the action of ferments.

Dr. Lotsy dealt with examples of heterogenesis in conifers. The expressions heterogenesis (Korschinsky, "Flora," 1901), mutation and spontaneous variation have practically the same meaning, and are applied to phenomena which illustrate one method by which new species may be formed. The author exhibited a specimen of *Capsella Heegeri*, given to him by Count Solms-Laubach, who recently described this species as a new form which appeared to have arisen suddenly from *Capsella bursa pastoris* (*Bot. Zeitung*, 1900). Reference was made to Hugo de Vries' important publication ("Mutationstheorie") in which several new species are described as having been formed as the result of sudden variations, which were manifested during certain periods of spontaneous variation. Dr. Lotsy drew attention to two genera of conifers—*Cupressus* and *Thuya*—which he described as passing through a period of spontaneous variation. Among a large number of seedlings of *Cupressus Lawsoniana* two plants were raised which exhibited marked differences—*C. Lawsoniana Wisseti* and *C. Lawsoniana lycopodioides*, forms which would undoubtedly be described as new species if their common origin were not known. *Thuya occidentalis Spaethi* was also described as a new form which had been produced as the result of sudden variation.

Mr. John Paterson read a paper in which he dealt with the biology and anatomy of *Stellaria holostea* and allied species. He gave a brief comparative account of the anatomical structure in *Stellaria graminea*, *S. media*, *S. glauca* and other Caryophyllaceæ.

Mr. W. C. Worsdell submitted a paper on the morphology of the ovule; an historical sketch. The same author communicated a note on the morphology of the "flowers" of *Cephalotaxus*, containing an account of original observations on proliferated inflorescences and flowers, which afforded evidence in support of the foliolar theory of the ovule as put forward by Celakovsky.

Physiology, &c.—Prof. Kny (Berlin) read a paper on Correlation in the growth of roots and shoots, in which he dealt with certain criticisms directed by Heering (*Pringsheim's Jahrb.*, 1896) against a communication on the same subject published by the author in 1894 (*Annals Bot.*). In the first paper the final results, and not a detailed account of the experiments, were published. Prof. Kny stated that his recent experiments had shown that in cuttings of *Ampelopsis quinquefolia*, as in those of certain species of *Salix*, the continual removal of the young shoots was soon followed by a less vigorous development of roots, and *vice versâ*. In *Salix* the retarding influence is first apparent in the roots, while in *Ampelopsis* the shoots were found to be the more sensitive.

Dr. F. F. Blackman and Miss Matthaei contributed a paper on natural surgery in leaves (*Annals Bot.*, 1901). If patches of leaf-tissue be killed in any way, the leaf reacts by forming an "absciss"-line round the injured spots at a little distance off in the healthy tissue. Separation soon takes place at this "absciss" line, so that the dead tissue which might be a source of danger is cut right round and drops out of the leaf. The same authors gave a paper on the relation between CO_2 production and vitality. This communication chiefly dealt with the effect of loss of water upon the CO_2-production in leaves. Even a small loss of water causes a very marked increase of the CO_2, and this effect continues until the water is restored

On the absorption of ammonia from polluted sea-water by *Ulva latissima*, by Prof. Letts and John Hawthorne. In a previous research (*Proc.* Roy. Soc. Edin. 1901) it was shown that the occurrence of this sea-weed in quantity in a given locality is associated with the pollution of the sea-water by sewage, the evidence being of three kinds: (1) The high proportion of nitrogen contained in the tissues of the *Ulva*; (2) an examination of certain localities in which the sea-weed occurs in abundance, and of others from which it is virtually absent; and (3) experiments on the assimilation of nitrogenous compounds by the growing *Ulva* from sea-water artificially polluted.

The following conclusions were drawn from recent experiments:—(1) The absorption of ammonia by the sea-weed is very rapid, and with the mixtures used practically all the ammonia was absorbed in five hours (with one exception, when 75 per cent. was lost). (2) The amount absorbed is greatest during the first hour of contact, and then rapidly falls off. (3) Although the concentration of the ammonia exercises some effect on the proportion absorbed, it is by no means so considerable as might have been expected. (4) The sea-weed absorbs ammonia both in daylight and in darkness, but the proportion in the latter case is rather less than in the former. (5) The effects of an increased area of the sea-weed on the proportion of ammonia absorbed are not so great as might have been expected. These results may be of practical importance in those districts where a serious nuisance results from the decay of large quantities of the *Ulva*, which have been washed ashore, or have accumulated in shallow water.

The diameter increment of trees, by A. W. Borthwick. There are two methods by which the rate of growth in thickness or diameter increment of trees can be ascertained. One of these methods is to measure annually or at certain intervals the diameter or circumference by means of tree callipers or a tape. The only other method of investigating the diameter increment on standing trees is by means of a very useful instrument known as Pressler's increment-borer. Mr. Borthwick stated that through the kindness of Prof. Bayley Balfour he had recently had the opportunity of testing whether the increment-borer would yield the same results as those furnished by the tape. A comparison of results showed a close agreement between the two methods.

Dr. R. J. Anderson described an apparatus for studying the rate of flow of solutions in plant stems, and gave a preliminary account of experiments on which he is at present engaged.

On the strength and resistance to pressure of certain seeds and fruits, by Prof. G. F. Scott Elliot. The author described experiments which he had made in order to determine the amount of weight which seeds can endure without breaking. The experiments were generally conducted by means of a spring balance weighing up to 50 lbs.; seeds and fruits which withstood a pressure of 50 lbs. were tested with a Wicksteed's single-lever vertical testing machine. The paper dealt also with the relation between the resisting power and the shape and structure of seeds. Attention was called to various peculiarities of fruits and seeds which serve as important aids to their resisting power.

Forestry.—Mr. Samuel Margerison communicated a paper on the transport of British timber. He drew attention to the fact that imported fir sold at a less price than that at which British fir can be delivered, and urged the desirability of bearing in mind the question of transport in the scientific development of our forests.

Mr. G. P. Hughes gave an account of Government plantings in the Isle of Man.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Mr. David B. Monro, Provost of Oriel, succeeds the Rev. Dr. Fowler, President of Corpus Christi College, as Vice-Chancellor.

CAMBRIDGE.—The moderators for the mathematical tripos, 1902, are Mr. W. Burnside, F.R.S., Pembroke, and Mr. J. Greaves, Christ's. The examiners are Mr. J. G. Leathem, St. John's, and Mr. J. H. Grace, Peterhouse.

The outgoing Vice-Chancellor, Mr. Chawner, Master of Emmanuel College, in his valedictory address, stated that the amount received for the Benefaction Fund was more than 66,000*l*. This, though it falls short of what is required even for the pressing needs of the University, has made it possible to enter into contracts for the Botany School, and a substantial portion of the Medical School buildings. Dr. Lawrence Humphry has been appointed assessor to the regius professor of physic, and Sir R. S. Ball an elector to the Isaac Newton scholarships. Prof. W. R. Sorley has been elected to a professorial fellowship at King's College. Prof. Somerville has informed the Vice-Chancellor that, having accepted a post in His Majesty's Board of Agriculture, he will resign the chair of agriculture at the end of the present term. Mr. K. Lucas, of Trinity College, has been nominated to occupy the University table in the Marine Biological Laboratory at Plymouth. Mr. J. H. Jeans, second wrangler 1898, Smith's prizeman 1901, and Mr. H. A. Wilson, research student in physics 1899, have been elected to fellowships at Trinity College.

IN delivering the opening address of the winter session of St. Andrews University last week, Principal Donaldson spoke on the subject of Mr. Carnegie's recent gift and the relation of the universities to the trade and commerce of the country. With reference to the first part of his subject Principal Donaldson said that the gift of Mr. Carnegie rendered it possible for every Scotsman to obtain a university education if he was capable of it; its second purpose was to increase the usefulness and influence of the Scottish universities by furnishing them with lectureships, laboratories, scholarships of research, and every form of equipment that could enable them to do their work most effectively. It was impossible to estimate the value of this part of the gift, of the possibilities which it created, and of the good that it would do to the whole community. It would bring all the various departments of study up to a high level, and especially it would promote in the highest degree original inquiry and investigation. For want of means they had fallen behind in this department, but the difficulties were now removed. Every student who had the ability to conduct original research would have his opportunity, and they might expect Scotland to take a foremost place in those scientific discoveries and inventions which were the prominent feature of our age.

SPEAKING on Saturday last to the Medical Faculty of University College, Liverpool, Prof. Oliver Lodge, F.R.S., Principal of Birmingham University, said a year ago he did not expect to find the full University ideal so prominently to the front; but any hesitation that might have been felt at urging it too hastily or inopportunely had been removed by the resolution of their council—their college council and likewise their city council—that a University for Liverpool was a necessity, and that any step towards furthering of that object would be welcome. The multiplication of municipalities, said Dr. Lodge, was wholly good. Why should the multiplication of Universities be considered bad? Let every city become a University when it was worthy, but it must make itself worthy first. Proceeding, he said that one of the functions of a University was the increase or improvement of knowledge, what was called "research." The ancient formula of the Royal Society stated that it existed "for the improvement of natural knowledge." He commended to their notice this word "improvement." Their primary aim should be improvement. The guardians of knowledge must be improvers of it, else it began to decay and to be lost. A University was the corporate repository of learning, not of ancient learning only, but of modern learning too; the most recently discovered fact of science there found its natural guardians, and there it was that new facts should be born. He commended this notion of "improvement of knowledge" to students, to every class of student. An atmosphere of constant effort towards the improvement of knowledge, with the accompanying stimulus of potential discovery; this was the atmosphere that should enfold every earnest student who entered the portal of a modern University.

THE new department of pathology of the University of Oxford was formally inaugurated on Saturday last. The building, which has been erected at the cost of about 10,000*l.* (5000*l.* of which was the gift of Dr. Ewan Fraser, of Balliol College), occupies a site at the back of the University Museum. It is rectangular in shape, measuring 75 feet by 65 feet, and consists of a basement and two storeys, the rooms being grouped round a central vestibule. Amongst the latter are a lecture room, a museum, laboratories for the teaching of morbid histology and of bacteriology, research rooms for work in experimental pathology and in chemical pathology, and various store rooms, attendant's work room, workshop, and cold-room are also provided. Sir William Church, president of the Royal College of Physicians, in delivering the opening address, said that the eightieth anniversary of the birthday of the Nestor of pathological research, Prof. Virchow, being that day celebrated. Oxford could not in a more worthy way pay its homage to the veteran man of science. Just at the time that their museum was being erected, Prof. Virchow gave to the world his memorable work, "Die Cellular Pathologie," which placed pathology on a new foundation and taught them to regard pathological processes as the perversion of physiological ones, influenced by various disturbing agencies. Pathology could not be studied without physiology, neither could physiology in its completeness be carried on without pathology, and more especially had this become manifest since they had been acquainted with the part played by micro-organisms in the universe, and the influence they had on living structures. A knowledge of both physiology and pathology was indispensable for those who would practise medicine; but to regard pathology as a mere adjunct to medicine was to take a narrow and erroneous view of the processes of nature. As a physician he could not but regard with extreme satisfaction the addition which had been made to the opportunities afforded to their medical graduates for the acquisition of scientific knowledge, but he was far from looking upon the technical work which would be done in direct connection with medicine as the only, or, indeed, the main, advantage which would accrue from it. Pathology at the present time was, above all others, that section of medical science which offered the widest promise of progress, and by the original research which under the guidance of the able head of their pathological department would there be carried on, he trusted that real advances in knowledge might be made which both directly and indirectly might benefit mankind, and that in pathology, as in the other departments of science, Oxford might hold an honourable record

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, October 7.—M. Bouquet de la Grye in the chair.—On the extension of a formula of Euler and on the calculation of the principal moments of inertia of a system of material points, by M. K. Bohlin.—General properties of couples of kinematic elements, by M. G. Kœnigs.—The action of urethane on pyruvic acid, by M. L. J. Simon. Pyruvic acid combines directly with urethane without the use of any condensing agent, the compound $CH_3.C(NH.CO_2C_2H_5)_2CO.OH$ being formed. The ethyl ester of this substance can also be obtained by condensation of ethyl pyruvate with urethane, but in this case a little hydrochloric acid is necessary to assist the reaction Boiling with dilute acid readily regenerates the pyruvic acid.—On monobromomalonic dialdehyde, by M. R. Lespieau. This substance is formed by the action of bromine in bright sunlight upon the substance $CHBr:CBr.CH_2OCH_3$. Owing to its forming a potassium salt it was at first taken for an acid, but its aldehydic nature is clearly established by its reactions with Schiff's reagent, and the formation of phenylbromopyrazol with phenylhydrazine.—On the reducing properties of certain nitric esters, by MM. Leo Vignon and F. Gerin. The nitric esters derived from methyl and ethyl alcohols, glycol and glycerol do not reduce an alkaline copper solution. Tetranitroerythritol possesses faintly reducing properties whilst a strong reduction is produced by the nitrates of dulcitol and mannitol.—Experimental researches on the excitability of the spinal marrow, by M. Alex. N. Vitznou. It is shown that, contrary to the results of previous experimenters, the grey matter of the spinal column can be excited by electric currents, and that there is a clear difference between the reactions which are produced as a consequence of the stimulation of the antero-lateral cords and those resulting from the stimulation of the grey matter, the latter producing generally tetanic movements. The grey substance can also be excited by simply mechanical means, if care be taken that there is as little loss of blood as possible during the preliminary operation.—The influence of spermotoxin upon reproduction, by Mlle. C. de Leslie. If some spermotoxic serum furnished by a guinea-pig is injected into a white mouse, the latter loses its power of reproduction, the sterility being maintained for from sixteen to twenty days.—On the liberoligneous elements of ferns, by MM. C. Eg. Bertrand and E. Cornaille.—Double flowers and parasitism, by M. Marin Molliard. In two cases (*Primula officinalis* and *Scabiosa Columbaria*) in which a tendency to form double flowers was observed, it was found that the roots were attacked by parasitic fungi, and it appears very probable that it is to these parasites that the changes in the flowers must be attributed. The author points out that these facts may have important applications in practical horticulture.—An experimental contribution to the study of the physical signs of intelligence, by M. N. Vaschide and Mlle. M. Pelletier. As the result of measurements made on more than 300 children it was found that the cephalic development of the intelligent subjects was different from an anthropological point of view from the unintelligent subjects. The most marked difference is in the magnitude of the auriculo-bregmatic measurement.

THURSDAY, OCTOBER 24, 1901.

LIFE BY THE SEA-SHORE.

Life by the Sea-shore: an Introduction to Natural History. By Marion Newbigin, D.Sc., &c. Pp. viii + 344. (London: Swan Sonnenschein and Co., Ltd., 1901.) Price 3*s.* 6*d.* net.

MANY of the people who now live on the coast, or of the constantly increasing numbers who periodically migrate for a few weeks to the sea-side, must have often felt the need of just such a book as the one before us. It is suited to the junior student or the amateur who as yet knows little or nothing of marine life; it is moderate in size and price, and contains a wonderful amount of information; it is almost as refreshing as a dip in the briny itself, and in the treatment of its subject-matter it reminds us of Charles Kingsley's "Glaucus" and of Philip Gosse's "Year at the Shore," and other charming works of a former generation. We in Britain are a maritime people, we owe much to the sea, and we boast on all appropriate occasions of our connection with it. Surely, then, we ought all of us to have some elementary knowledge of oceanography—of our seas and their ways and their inhabitants. British naturalists in the past have done much to enrich marine zoology by splendid monographs, such as those of the Ray Society and some of Van Voorst's series; but the public at the sea-side cannot be expected to read monographs—or to understand them if they did—and the volumes of Gosse are out of print, and moreover are somewhat antiquated both in nomenclature and science.

The present little book by Dr. Marion Newbigin is quite up to date, and although scientifically accurate and sound is so delightfully simple that it can be read and comprehended by anyone at the sea-side who can collect common shore animals and compare them with the printed pages. It is food for babes compared with the monographs, but is at the same time sufficiently nourishing and stimulating to lead to the healthy development of sturdy young marine zoologists. Judging from the results I have had with some average school-girls of fifteen to eighteen upon whom it has been tried during the last few weeks, I should expect that this book will give rise to many delightful collecting expeditions, and after-hours full of intellectual pleasure when observing and identifying the specimens and reading up and verifying their characteristics. It is satisfactory, by the way, to see that Miss Newbigin insists upon the educational value of a certain amount of collecting and of species work—"and the identifying of species, though now sadly out of fashion, is an occupation which may yield one of the subtlest of pleasures." "So much of the present-day academical teaching seems to have [a certain] result, that I cannot but urge anyone beginning open-air studies to find some time for species work, and for this habits of patient and minute observation are essential," &c. (p. 25).

Our author is already known to zoologists from her papers on the pigments of Crustacea and other animals and her little book on "Colour in Nature." The present book, she tells us, is based upon a course of lectures—given presumably to Edinburgh students, as most of the animals dealt with, or chosen as types, are common east coast forms, and as a result one occasionally comes upon a remark that does not apply to other parts of our sea.

After a couple of introductory chapters on the conditions of shore life and the general characteristics of shore animals, such as shells, burrowing, weapons, partnerships, masking, larval characters, classification, hints as to methods, and so on, Chapter iii. starts with sponges and goes on to zoophytes. Then sea-anemones, worms, echinoderms, crustacea, molluscs, fishes and ascidians occupy the next twelve chapters, after which is a final section on the distribution and relations of shore animals, a list of works of reference and a double index. On the whole, perhaps the section on the higher Crustacea is the most full and satisfactory. The crabs seem especially well done, and also the polychætes. More space than the passing reference on p. 27 should have been given to the Protozoa. It is useless to pretend that the subject-matter of this book can be worked through without the microscope, and if that instrument is required for the triradiate spicules of the calcareous sponge, why should it not be applied to show us *Noctiluca* and *Ceratium* and *Rotalia* and *Folliculina* or some other equally common and important shore Protozoa? A short section on a few of the more abundant diatoms also would be justified by their great importance in connection with the food of animals in the sea, and ultimately of man.

One would rather not make any critical remarks—but few are needed—and if certain points are now noted which may seem to detract to some extent from the value of the book, they are not put forward in any fault-finding spirit, but are to be regarded rather as suggestions which may be of use to the author when a second edition is called for. There is a certain want of proportion in the amount of space allotted to different groups. For example, we find more than twenty pages, and a dozen figures, on the hydroid zoophytes, and less than twenty lines (no figures) on the Polyzoa, which are so constantly associated with the hydroids in shore pools and on seaweeds such as *Fucus* and *Laminaria.* It is difficult to see any reason for this and a few other cases of arbitrary selection. The two groups occur together, the Polyzoa are usually the more abundant and striking, the same methods of collecting and examining apply—the pocket lens will show a certain amount of the structure of the colony in each case, but a microscope is really necessary for both. And as to the æsthetic pleasures derived from beauty and charm of movement, I find that the commonest of shore Polyzoa—such as *Flustrella hispida*, found all round our coasts, in profusion, on *Fucus*—alive in a watch-glass of sea-water under even a low power of the microscope, protruding and retracting its crown of ciliated tentacles, is one of the most fascinating objects that can be shown to, or found by, the young naturalist on the sea-shore, and one of the most easily obtainable from which to demonstrate ciliary action and to give as an example of an animal collecting food by causing currents in the water.

I have alluded to the inadequate treatment of Protozoa. A more serious omission even is that of the Copepoda, a group of great importance amongst marine animals on account both of its numerical strength and of the activity and utility of its members. It is true that very many of these are obtained from the surface of the sea and not strictly from the shore, but that same remark applies equally to the medusoids discussed and figured in Chapter iii., and it would be difficult to catch the medusoids without seeing Copepoda also. But there are also plenty of shore-haunting copepods to be obtained very easily with a muslin hand-net in pools, or from sand and mud at low tide, and under stones. A small boy of six has just brought me a cup full of bright red ones (*Harpacticus fulvus*) which he caught himself with a sixpenny hand-net along the edge of the sea and in pools, where they are quite visible to the eye. He wanted to know what they were and how they jumped, and his little sister of two-and-a-half added the important question, "Why are they so red?" If Miss Newbigin would answer these questions—and no one is more competent than she to deal with the last one—it would help not only the children, but their seniors. *Harpacticus* is sometimes very abundant in pools far up the shore, where their red bodies are quite conspicuous on the green *Enteromorpha*, and they are eaten with avidity by young blennies, sticklebacks and other little shore fishes. "*Why are they so red?*"[1]

The "keys for identification" and other similar tables of characters at the ends of chapters are of doubtful utility. They are, of course, incomplete; they only deal with a few selected genera and species in each section, and yet from their form they give the deceptive impression of a complete classification; they lead to a good deal of repetition and give little information beyond what is in the text—a considerable saving of space would be effected by their removal. What is the difference between "legs very slender and long" given as a character of *Phoxichilidium*, and "legs very long and slender" as a character of *Nymphon* in the table on p. 224?

Dissection of the types chosen and details of internal structure have, probably quite wisely, been avoided; but under those circumstances some statements in the book, such as that "the heart is in front of the gill" (p. 248) given as a character of the opisthobranchs, will probably be found meaningless to readers without further knowledge than the book gives. Even one simple anatomical diagram of the type form of each group would have been a useful addition.

There are, of course, other points of detail in connection with which alterations might be suggested. *Asterina gibbosa*, very common in shore pools amongst *Corallina* on some parts of the coast, might be added to the star-fishes discussed. The presence of thread-cells in the cerata of *Eolis* is an interesting point worthy of mention. *Trochus zizyphinus* (p. 236) is not merely an inhabitant of deep water, but is common, alive, between tide-marks on some of our shores. On the whole the figures are good, but *Alcyonium* (p. 16), *Polycarpa* (p. 295) and *Pleurobrachia* (p. 330) are not satisfactory.

The style of the book is easy and pleasing—lively even in places, as on p. 277, where the author describes how she first made acquaintance with the grace and beauty of the living *Lima hians* when released from its woven nest of shells and weeds. In conclusion, it is a pleasure to cordially recommend "Life by the Sea-shore" as a charming and useful holiday companion which will not only give much information, but will also serve as a good introduction to one of the most fascinating branches of modern science.

W. A. Herdman.

[1] Obviously, there are two kinds of answer—the one in terms of lipochromes and the other in terms of natural selection.

SCIENTIFIC TOPOGRAPHY.

Recherches sur les instruments, les méthodes et le dessin Topographiques. By Colonel A. Laussedat. Tome ii. Part i. Pp. 198. (Paris: Gauthier-Villars et Fils, 1901.)

IN the first part of the second volume of his exhaustive treatise on topography, Colonel Laussedat treats of "iconométrie" and "métrophotographie"—two branches of the art which are but little studied in British military schools. He commences by tracing the evolution of the photo-theodolite from the primitive forms of the camera obscura and the camera lucida; and not the least instructive part of this volume is to be found in the careful analysis of those principles of perspective which are the governing principles of all methods of reducing a field of observation to its horizontal plan, whether for the purpose of topography or of plan drawing. He shows that the camera lucida is an instrument which (in France at any rate) has proved of immense value in the hands of the military engineer. Some excellent examples are given by Colonel Laussedat of the practical use that has been made of this instrument in the construction of accurate geometrical views of fortifications, with the object of obtaining precise plans of the same, on the principle which was first advocated by Beautemps-Beaupré, and which is fully explained by the author. It is curious that an English invention (it was invented in 1804 by Wollaston) should have been applied to so much greater practical purpose in France than it ever has been in England.

From camera lucida drawings of the elevation of a line of fortifications, or of buildings taken from two or more points of view, French engineers have found it possible to construct accurate plans of the same fortifications on precisely the same principles which now lead to the definition of topography from photographs. With this instrument, combined with a telescopic enlargement of the field of view, the defenders of Paris during the last memorable siege were able to construct a fairly accurate panorama of the German advanced positions around the city, to note the daily and hourly changes in those positions, and to keep the military authorities perpetually supplied with most important information which would otherwise have been impossible to attain. In his concluding chapter Colonel Laussedat renders a well-deserved tribute of recognition to those many assistants (astronomers, doctors, engineers, artists and architects) who all brought the necessary technical artistic skill to his assistance and maintained that remarkable record. In England the camera lucida is still recognised as an important aid to the illustration of geological phenomena. But its capabilities as a military instrument have been hardly recognised.

From the camera lucida to the photo-theodolite is a natural process of evolution, and the best half of the volume is devoted to its illustration. The application of photography to surveying has already been well tested in many European fields, as well as in America. Some tentative efforts are now being made to introduce the photo-theodolite to India, but the results are hardly mature enough to justify any opinion as to their success. In France photo-topography has been chiefly applied to the field of that which we should term in England "revenue" or "cadastral" survey; and in Canada (a fact which is not recognised by Colonel Laussedat) a still wider opening has been afforded by the Geological Survey, which is practically a small scale topographical survey leading to the first general map of the country. There are, at any rate, records sufficient to enable us to bring the test of actual experience in other countries than France to bear on Colonel Laussedat's estimate of the capabilities of the system. That estimate appears to be absolutely favourable, but it must be contended that the illustrations which support Colonel Laussedat's opinion are not in themselves comprehensive enough to justify the conclusions at which he arrives, which would apparently include all classes of reconnaissance, or survey, in all conditions of ground as suitable for its application.

An official examination into the results of a photo-theodolite survey was conducted in Paris as long ago as the year 1859, and the report of the commissioners nominated by the Academy of Sciences was so favourable that in 1863 a "photo-topographic brigade" was formed, under the direction of Laussedat, which executed surveys on comparatively large scales (from 1/1000 to 1/20000), and which lasted for a period of eight years. The brigade was broken up in 1871, and whilst Colonel Laussedat refrains from commenting on the reasons for its suppression, he clearly indicates that it was for no reason which implied technical failure.

Various modifications of the original system are discussed or recommended, and one or two excellent illustrations of the resulting surveys are given at the end of the book. But it must be noted that the field of survey to which this process has been applied in France is after all but local, and the scale of mapping is comparatively large. For instance, we find in Plate xiii. a reproduction of about 15 square miles of country, originally surveyed on a scale approximating to 12 inches per mile (reduced to one-fourth in reproduction), to which the following details are appended. The survey was completed in ten days in the field, supplemented by two and a half months of subsequent work in the drawing office (bureau). It involved the use of fifty-two photographs, which were taken at thirty-one stations. Of these stations eighteen were stations of triangulation, and the rest "supplementary." The map itself is fully contoured and apparently quite up to the standard, in detail, of maps on a similar scale executed by the English Ordnance Survey. The time (and consequently the expense) involved in its production will of course compare favourably with that of any other known system of surveying; but it would be rash to infer therefrom that photo-topography is under all conditions either a cheap or a rapid method of surveying. In Canada good work has been done by this process on the smaller scales of one inch or two inches per mile, and the system generally is well established. But Canadian surveyors are not prepared to advocate it in entire supersession of the more widely known system of plane table topography based on triangulation, maintaining that its advantages are confined to comparatively restricted conditions of surface conformation. Thirty-one stations of observation in fifteen square miles of country (giving an average of two "fixings" per square mile) may under certain conditions be sufficient to enable a surveyor to see into the topographical detail of ridge and furrow, plain and gully, that the country presents, and result in a creditable map. But in a vast proportion of the broken and rugged districts presented by the varied physiography of Asia, Africa, or America two stations per mile would certainly not be sufficient, and the accumulation of photographs would rapidly become an unwieldy burden. When we consider the requirements of geographical surveys on yet smaller scales (say 1/500000) it is impossible to concede that the recognised systems of rapid plane tabling in experienced hands, which result in daily outturns which may be reckoned in scores of square miles of finished mapping (no "bureau" work is required by a really well-trained topographer), can be surpassed in rapidity by any more complicated process which has yet been invented.

Possibly the discussion of the application of photography to this most important field of geographical survey may be reserved for a future volume, although it might certainly have been usefully included in the present one. The author is at any rate on perfectly sound ground when he recommends every explorer who makes use of photography for illustrative purposes to fix the position of his views and the direction (or azimuth) of them with careful exactness on his route map; with the assurance that in scientific hands they will prove of immense value in elucidating the topography of the country which they illustrate if they are thus registered.

There is no work in the English language equal to that of Colonel Laussedat as a comprehensive and up-to-date review of the history and development of topography; in the value of its scientific deductions and illustrations; or in the interest which is sustained by the literary skill exhibited. It should find a place in every library of civil or military engineering institutions which professes to maintain an efficient stock of standard works for reference.

T. H. H.

EUCLID REVISED.

Euclid's Elements of Geometry. Books i.-iv., vi. and xi. By Charles Smith, M.A., and Sophie Bryant, D.Sc. Pp. viii + 460. (London: Macmillan and Co., Ltd., 1901.) Price 4*s*. 6*d*.

IF Euclid is to continue as the foundation of geometrical teaching in our schools, this work must be very warmly welcomed. The exact order of Euclid is followed, but (as the editors inform us) with no special regard to the exact words of the translation of Simson (who for a moment becomes "Simpson" in the foot-note on p. 79). There is also a complete absence of the mechanical chopping up of each proposition into separate blocks under the heads of "general enunciation," "particular enunciation," "hypothesis," "construction," "to prove," "proof," "conclusion," which in some text-books, and in the minds of many boys, has reduced the whole subject to an artificial jargon.

Mrs. Bryant, both as an expert logician and as the daughter of a fellow of Trinity College, Dublin (Rev. W. A. Willock), who had no belief in the appropriateness of Euclid's book except to "grown-up, hard-headed, thinking men," was sure to remove from the path of the young pupil as much of the essential difficulty of Euclid as could be removed consistently with the retention of the book as the basis of school instruction.

To follow the subject in detail, we notice that the editors have deliberately left out alternative proofs of the "Asses' Bridge" on the ground that Euclid's proof is found by experience to be more readily understood than any of the alternative proofs—a statement which surely cannot be well founded. What can be more simple than the proof founded on the superposition of two identical triangles? And, again, if we imagine the bisector of the vertical angle to be drawn, we have the result as a direct consequence of prop. iv. It is not to the point to object that Euclid will not allow us to imagine this bisector unless we can show how to draw it; if the bisector were drawn, the result would follow—that is proof enough. At the end of Book i. there is a large collection of worked-out theorems and problems; and we may specially notice the excellent exposition of the method of analysis and synthesis in pp. 102–106, which will greatly help the pupil who is learning this method of attacking problems. Besides these worked questions, there is a collection of 100 unworked exercises in illustration of Book i.

In Book ii. the fundamental propositions 12 and 13 are proved as an extension of the proposition of Pythagoras (47, Bk. i.) by the famous old windmill figure so familiar to us all; and, as the editors inform us, this proof is found in Lardner's Euclid, but cannot be traced further back. It is strange that the editors of our school Euclids should have overlooked this most interesting and graphic proof. Lardner's Euclid, now seldom seen, is—even compared with the best modern editions—a work of great usefulness and high merit.

There is a note at the end of Book ii. (p. 148) the substance of which is that pure geometry must be kept severely apart from all arithmetical conceptions; and this is followed (p. 150) by a still more remarkable note stating that "in all examinations" the use of + and −, of the abbreviation AB^2 for *the square on* AB, and of the abbreviation AB . BC for the rectangle AB, BC, is permitted in writing out all theorems and problems of geometry, provided that these are not given in Euclid's text.

Why such an extraordinary distinction and restriction should exist is incomprehensible to us, and remains so even after we have read the excuse put forward for it by the present editors; and after this excuse comes the statement

"the use of these symbols ought never to be allowed at any time until it is clear that AB^2 and AB . BC are used by the student simply as the shortest way of writing the square on AB and the rectangle contained by AB and BC, respectively."

Thus the divorce of all arithmetical conception—and, indeed, all quantitative conception—from geometry is advocated; and if the restriction were really carried out both by teachers and by examiners (which it is not), the teaching of the subject would be rendered much more slow and difficult than it is at present.

Book iii. ends with a very large collection of worked-out questions followed by 100 exercises, a very good feature being the association of each famous result with the name of its discoverer; and a similar remark may be made with regard to Book iv. Book v. is omitted, only the definitions required in Book vi. being given. Euclid's test of proportion—*i.e.* of the equality of the ratio A : B to the ratio C : D—is given and applied to six special cases (p. 293) under the heading "Theory of Proportion." This test is, of course, that C : D will be the same as A : B if when $mA \gtreqless nB$ we have $mC \gtreqless nD$; and we wonder whether any beginner in the world is introduced to the notion of the equality of ratios by this means. Probably without a single exception, every boy is first told that 4 : 2 is the same as 6 : 3, because 2 is contained in 4 just as often as 3 is contained in 6; and even if the one quantity were not contained an integer number of times in the other, he would be prepared to admit and understand the equality of ratios if this number was an endless decimal, provided it was the same for the two compared ratios. Euclid's test must infallibly be received by the beginner merely as the *ipse dixit* of Euclid; the beginner cannot understand its validity apart from arithmetical notions; and it seems rather grotesque to find it formally employed to prove such a trifle as "magnitudes which have the same ratio to the same magnitude must be equal." Lardner has, as usual, some excellent remarks on this criterion; but his exposition amounts to no justification that could possibly convince the mind of a beginner. Hear also the opinion of the Rev. W. A. Willock on the question ("Elementary Geometry of the Right Line and Circle," p. ix.):—

"The criterion of proportion used is that of Elrington, by *sub*multiples. This test is here adopted because it is more readily understood by young students, and also more conformable to the common notions of proportion. Moreover, it holds good, in all strictness, for commensurable magnitudes; and, as to the incommensurable, it holds equally good if the equisubmultiples taken of the first and third terms be infinitesimals. . . . The right conclusion as to the two tests is, probably, that both should be given in a treatise on elementary geometry, each having its own peculiar advantages."

At the end of Book vi. follows what may be regarded as a small encyclopædia of important results and methods—coaxal circles, harmonic ranges, poles and polars, centres of similitude, inversion, maxima and minima, &c.—an invaluable collection, excellently handled.

Book xi. calls for no detailed remarks: its accompanying illustrations are of the same high order of merit as that which characterises all the special work of the editors.

OUR BOOK SHELF.

The Life-History of British Serpents and their Local Distribution in the British Isles. By Gerald R. Leighton, M.D. Pp. xvi + 383. 8vo. Illustrated. (London: W. Blackwood and Sons, 1901.) Price 5*s*. net.

THE idea of supplying the "field-naturalists of the British Isles" with a handbook dealing with the life-history of the native snakes and their distribution is an excellent one. The existing treatises on British reptiles are either antiquated or compiled by writers insufficiently versed in the subject. It is only regrettable that Dr. Leighton, whilst engaged in the preparation of this little work, which contains much interesting matter, should not have made himself more thoroughly acquainted with what has been published on the subject, in England at least, as we notice the omission of important information which might have been obtained through reference to the volumes of the *Zoologist* and to the British Museum Catalogue of Snakes, of which he appears to be ignorant. The descriptions of the three species which make up the British ophidian fauna are inadequate, and this is all the more to be regretted since many points of structure and coloration which are subject to variation would have afforded an important topic in which to arouse the interest of the field-naturalist.

The reproduction of many of the photographs which are liberally scattered through the work leaves much to be desired, and the figures of the head-shields of the ring-snake or grass-snake and the smooth snake, as well as of the scales round the eye in the adder, are very inaccurate. True, the work is only intended for the non-scientific, who may perhaps not feel inclined to be too exacting on these points, if we bear in mind how few have the necessary training of the eye, in matters reptilian, to detect inaccuracies which would hardly be tolerated if they applied to birds or insects.

The book is made up to a great extent of letters from correspondents and of newspaper cuttings referring to distribution, size and habits, the adder's "swallowing of the young for protection" being, of course, the heading of an important chapter. All this is very useful and interesting information, and is well commented upon by the author.

It is not without surprise that we notice an attempt to restore the "small red viper," *Coluber chersea* of Linnæus, to the rank of a distinct species, under the new name of *Vipera rubra*, which is regarded by the author as "quite as distinct from the ordinary adder as a swallow is from a martin." On the other hand, Sowerby's *Coluber dunfrisiensis*, which still appears in the synonymy of the smooth snake (*Coronella austriaca*), is a distinct species, which inhabits North America and was erroneously ascribed to Scotland. In describing the common grass-snake it should have been stated that the yellow or orange collar is sometimes absent in adult specimens. It is held by most observers who have kept this snake that its food consists of nothing higher in the vertebrate scale than batrachians; but Dr. Leighton informs us that one of its most favourite meals consists of mice, and that it also feeds on water-voles and birds. The only instance known to the writer of this notice of a grass-snake containing a mouse is that of a sciagraph exhibited before a meeting of the Zoological Society of London a few years ago; but an inquiry elicited the fact that the mouse had been forcibly introduced. It is desirable that Dr. Leighton should adduce some more precise data in support of his statement.

In spite of the defects to which we have drawn attention, this little book will be of use and interest to field-naturalists, and will no doubt result in greater attention being bestowed on a somewhat neglected section of vertebrates. G. A. B.

The Feeding of Animals. By W. H. Jordan. Pp. xvii + 450. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1901). Price 5s. net.

THE author takes a wide range. Beginning with a popular account of the chemical constituents of plants and animals, the processes of digestion and nutrition, and the functions of food in the body, he then proceeds to a description of cattle foods, and to the actual results obtained by the use of food as ascertained by scientific investigations and farm practice. The book is written in a somewhat diffuse and popular style, and the different parts are of unequal merit, but it is of undoubted value. The author is not pledged to any special theories, but readily accepts every well-proved fact. He is well acquainted with the most recent German and American investigations, and has brought together a large number of very important new results, for which teachers will heartily thank him. Had the author written with greater accuracy for science students, instead of writing for the half-educated general reader, he would probably have produced a better book on the feeding of animals than has hitherto appeared in the English language.

The book is thoroughly American, and the author illustrates every part of the subject as far as possible by the investigations and practice of his own country. He is naturally bound by American conventions, and to one of these we must strongly demur. The whole of the nitrogenous substances present in any vegetable food are collectively spoken of as "protein," although, in fact, a large part of them may be amides, and in some cases nitrates. This is distinctly worse than the German plan of calling the whole group "Rohprotein," as in this case some qualification is expressed. The American nomenclature results in a confusion of language which must be abhorent to every physiological chemist. Thus our author says (p. 179): "A much larger part of the protein of roots consists of amides than is the case with the grains, the protein of the latter being correspondingly richer in albuminoids." It is surely far better to give the collective nitrogenous matters the general title of "nitrogenous substance" instead of applying to them the name of a particular body, which in some cases forms only a small part of the group. The error is all the more important as the amount of true proteids present in a food has generally a great influence upon its nutritive value.

The chapter by Mr. W. P. Wheeler on the feeding of poultry is of considerable importance, as he brings before us the results of many recent American investigations. R. W.

First Stage Building Construction. By Brysson Cunningham, B.E., Assoc.M.Inst.C.E. Pp. viii + 240. (London: W. B. Clive.) Price 2s.

THIS small volume on elementary building construction forms one of the "organised science series." It is intended for students preparing for the examinations in elementary building construction under the Board of Education. There are already several books published which cover the same course, but none, we believe, which profess to do so at the modest price of 2s., as does the volume before us. Mr. Cunningham's book does not call for much comment. The information given is of the kind required, and is well and tersely put in a practical way, but the diagrams, which are so important in a book of this kind, are in many cases very carelessly drawn, and do no credit to the book. If these are improved in a future edition, it will render the book more valuable.

Théorie Nouvelle de la Dispersion. Par M. G. Quesneville. Pp. 72. (Paris: A. Hermann, 1901.)

WE opened this book in the hope of finding an intelligent criticism of modern theories of dispersion and an attempt to substitute something better; but the author appears to be very imperfectly acquainted with them; for instance, there is no reference to Sellmeier, or to Lord Kelvin's Baltimore lectures. His criticisms are mainly directed to the writings of Cauchy. The "new theory" does not appear to include any new suggestion as to physical mechanism, or anything to repay the labour of wading through sixty pages of algebraic developments. J. D. E.

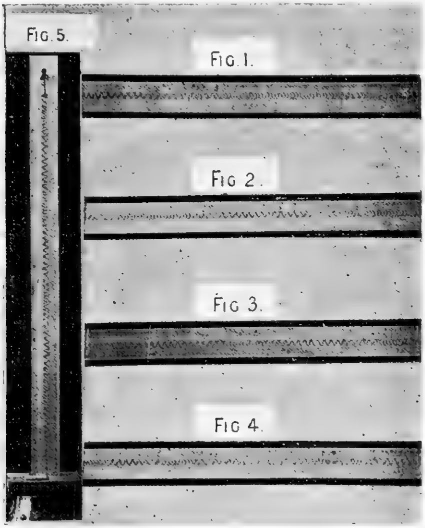
LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A Simple Model for Demonstrating Beat.

THE phenomenon of beat produced by the interference of two series of waves having nearly the same wave-length can be objectively represented by a model of simple construction.

A spiral, whose diameter and pitch are respectively 2 cm. and 2·5 cm., is made of a steel wire about 1 mm. thick and hung vertically before a white screen. At a distance of a few metres we observe a very regular series of transverse waves. Another spring of exactly the same dimensions is suspended in front of the first spring so as to coincide with each other when they are seen at a distance. If one of the springs is then slightly stretched, there results a small difference in wave-length of the two sets of waves, thus causing them to strengthen in one place and destroy in the other. The distance between these



two places becomes less as the difference of wave-length increases. Figs. 1, 2, 3, 4 are the photographs of the springs suspended in the manner just mentioned, and show successive stages of interference produced by stretching the length of the second spring. The result of interference of two such waves evidently corresponds to the phenomenon of beat.

For practical purposes, two springs are suspended from a vertical board, one in front of the other, as shown in Fig. 5. Both ends of the first spring are fixed, while the upper end of the second is likewise fixed and the lower end pulled downwards by means of a string passing through a hook attached to the stand. Standing at a distance in front of the springs we can gradually stretch the second spring by pulling the string and easily observe the corresponding stages of interference in its different phases. K. HONDA.

Physical Laboratory, Imp. Univ., Tokio, Japan, May 26.

Polar Exploration.

THE following sentence is extracted from an admirable notice of the Arctic explorer, the late Baron Nordenskiöld, by Prof. A. G. Nathorst, himself renowned as an investigator of the Polar regions:—

"It may perhaps be of interest at the present time to recall the fact that we in Sweden have always taken for granted that the leader of a scientific expedition must be a naturalist, to whom the commander of the vessel has to be subordinate."—*Geograph. Anzeiger*, ii. p. 129, September, 1901.

The marked success of the Swedish expeditions, not merely in pure science, but also in geographical discovery and the safe return of their members, gives this opinion weight as well as interest. Of course it is not what the president of the Geographical Section of the British Association calls "the good old British plan." CIVILIAN.

ON THE CLUSTERING OF GRAVITATIONAL MATTER IN ANY PART OF THE UNIVERSE.

IN the Mathematical and Physical Science Section of the British Association, Lord Kelvin delivered a discourse on "The Absolute Amount of Gravitational Matter in any large Volume of Interstellar Space." Gravitational matter, according to our ideas of universal gravitation, would be all matter. Now was there any matter which was not subject to the law of gravitation? He thought he might say with absolute decision that there was. They were all convinced, with their President, that ether was matter, but they were forced to say that the properties of molar matter were not to be looked for in ether as generally known to them by action resulting from force between atoms and matter, ether and ether, and atoms of matter and ether. Here he was illogical when he said between matter and ether, as if ether were not matter. It was to avoid an illogical phraseology that he used the title "gravitational matter." Many years ago he had given strong reason to feel certain that ether was outside the law of gravitation. They need not absolutely exclude, as an idea, the possibility of there being a portion of space occupied by ether beyond which there was absolute vacuum—no ether and no matter. They admitted that that was something that one could think of; but he did not believe any living scientific man considered it in the slightest degree probable that there was space surrounding our universe beyond which there was no ether and no matter. Well, if ether went through all space, then it was certain that ether could not be subject to the law of mutual gravitation between its parts, because if it were subject to mutual attraction between its parts its equilibrium would be unstable, unless it were infinitely incompressible. But here again he was reminded of the critical character of the ground on which they stood in speaking of or giving very definite propositions beyond what they saw or felt by experiment. He was afraid he must here express a view different from that which Prof. Rücker announced in his address, when he said that continuity of matter implied absolute resistance to condensation. They had no right to bar condensation as a property of ether. While admitting ether not to have any atomic structure, it was postulated as a material which performed functions of which they knew something, and which might have properties allowing it to perform other functions of which they were not yet cognisant. If they considered ether to be matter, they postulated that it had rigidity enough for the vibration of light, but they had no right to say that it was absolutely incompressible. They must admit that sufficiently great pressure all round could condense the ether in a given space, allowing the ether in surrounding space to come in towards the ideal shrinking surface. When he said that ether might be outside the law of gravitation he assumed that it was not infinitely incompressible. He admitted that if it were infinitely incompressible, then it might be subject to the law of mutual gravitation between its parts; but to his mind it seemed infinitely improbable that ether was infinitely incompressible, and it appeared more consistent with the analogies of the known properties of molar matter, which should be their guides, to suppose that ether had not the quality of exerting an infinitely great force against compressing action of gravitation. Hence if they assume that it extended through all space, ether must be outside the law of gravitation, that is to say, truly imponderable. He remembered the contempt and self-complacent compassion with which sixty years ago he himself, he was afraid and most of the teachers of that time looked upon the ideas of the elderly people who went before them, who spoke of "the imponderables." He feared that in this, as in a great many other things in science, they had to hark back to the dark ages of fifty, sixty or a hundred years ago, and that they must admit there was something which they could not refuse to call matter, but which was not subject to the Newtonian law of gravitation. That the sun, stars, planets, and meteoric stones were all of them ponderable matter was true, but the title of his paper implied that there was something else. Ether was not any part of the subject of his paper; what he dealt with was gravitational matter, ponderable matter. Ether they relegated, not to a limbo of imponderables, but to distinct species of matter which had inertia, rigidity, elasticity, compressibility, but not heaviness. In a paper he had already published he had given strong reasons for limiting to a definite amount the quantity of matter in space known to astronomers. He could scarcely avoid using the word "universe," but he meant our universe, which might be a very small affair after all, occupying a very small portion of all the space in which there is ponderable matter.

Supposing a sphere of radius $3·09.10^{16}$ kilometres (being the distance at which a star must be to have parallax 0″·001) to have within it, uniformly distributed through it, a quantity of matter equal to one thousand million times the sun's mass, the velocity acquired by a body placed originally at rest at the surface would, in five million years, be about 20 kilometres per second, and in twenty-five million years would be 108 kilometres per second (if the acceleration remained sensibly constant for so long a time). Hence if the thousand million suns had been given at rest twenty-five million years ago, uniformly distributed throughout the supposed sphere, many of them would now have velocities of twenty or thirty kilometres per second, while some would have less and some probably greater velocities than 108 kilometres per second; or, if they had been given thousands of million years ago at rest so distributed that now they were equably spaced throughout the supposed sphere, their mean velocity would now be about 50 kilometres per second (*Phil. Mag.*, August 1901, pp. 169, 170). This is not unlike the measured velocities of stars, and hence it seems probable that there might be as much matter as one thousand million suns within the distance $3·09.10^{16}$ kilometres. The same reasoning shows that ten thousand million suns in the same sphere would produce velocities far greater than the known star velocities, and hence there is probably much less than ten thousand million times the sun's mass in the sphere considered. A general theorem discovered by Green seventy-three years ago regarding force at a surface of any shape, due to matter (gravitational, or ideal electric, or ideal magnetic) acting according to the Newtonian law of the inverse square of the distance, shows that a non-uniform distribution of the same total quantity of matter would give greater velocities than would the uniform distribution. Hence we cannot, by any non-uniform distribution of matter within the supposed sphere of $3·09.10^{16}$ kilometres radius, escape from the conclusion limiting the total amount of the matter within it to something like one thousand million times the sun's mass.

Lord Kelvin then went on to compare the sunlight with the light from the thousand million stars, each being supposed to be of the same size and brightness as our sun; and stated that the ratio of the apparent brightness of the star-lit sky to the brightness of our sun's disc would be $3·87.10^{-13}$. This ratio (*Phil. Mag.*, August 1901, p. 175) varies directly with the radius of the containing sphere, the number of equal globes per equal volume being supposed constant; and hence to make the sum of the apparent area of discs 3·87 per cent. of the whole sky, the radius must be $3·09.10^{27}$ kilometres. With this radius light would take $3\frac{1}{4}.10^{14}$ years to travel from the outlying stars to the centre. Irrefragable dynamics proves that the life of our sun as a luminary is probably between 50 and 100 million years; but to be liberal, suppose each of our stars to have a life of 100 million years as a luminary, and it is found that the time taken by light to travel from the outlying stars to the centre of the sphere is three and a quarter million times the life of a star. Hence it follows that to make the whole sky aglow with the light of all the stars at the same time the commencements of the stars must be timed earlier and earlier for the more and more distant ones, so that the time of the arrival of the light of every one of them at the earth may fall within the durations of the lights of all the others at the earth. His supposition as to uniform density is quite arbitrary; but nevertheless he thought it highly improbable that there could be enough stars (bright or dark) to make a total of star-disc-area more than 10^{-12} or 10^{-11} of the whole sky.

To help to understand the density of the supposed distribution of 1000 million suns in a sphere of $3·09.10^{16}$ kilometres radius, imagine them arranged exactly in cubic order, and the volume per sun is found to be $123·5.10^{39}$ cubic kilometres, and the distance from one star to any one of its six nearest neighbours would be $4·98.10^{13}$ kilometres. The sun seen at this distance would probably be seen as a star of between the first and second magnitude; but supposing our 1000 million suns to be all of such brightness as to be stars of the first magnitude at distance corresponding to parallax 1″·0, the brightness at distance $3·09.10^{16}$ kilometres would be one one-millionth of this; and the most distant of our stars would be seen through powerful telescopes as stars of the sixteenth magnitude. Newcomb estimated from 30 to 50 million as the number of stars visible in modern telescopes. Young estimated at 100 million the number visible through the Lick telescope. This larger estimate is only one-tenth of our assumed thousand million masses equal to the sun, of which, however, nine hundred million might be either non-luminous, or, though luminous, too distant to be seen by us at their actual distances from the earth. Remark also that it is only for facility of counting that we have reckoned our universe as a thousand million suns; and that the meaning of our reckoning is that the total amount of matter within a sphere of $3·09.10^{16}$ kilometres radius is a thousand million times the sun's mass. The sun's mass is $1·99.10^{27}$ metric tons, or $1·99.10^{33}$ grammes. Hence our reckoning of our supposed spherical universe is that the ponderable part of it amounts to $1·99.10^{42}$ grammes, or that its average density is $1·61.10^{-23}$ of the density of water.

Lord Kelvin returned to the question of sum of apparent areas, the ratio of which to 4π, the total apparent area of the sky viewed in all directions, is given by the formula (*Phil. Mag.*, August 1901, p. 175) $\alpha \doteq \frac{3N}{4}\left(\frac{a}{r}\right)^2$; provided its amount is so small a fraction of unity that its diminution by eclipses, total or partial, may be neglected. In this formula, N is a number of globes of radius a uniformly distributed within a spherical surface of radius r. For the same quantity of matter in N′ globes of the same density, uniformly distributed through the same sphere of radius r, we have $\frac{N'}{N} \doteq \left(\frac{a}{a'}\right)^3$, and therefore $\frac{\alpha'}{\alpha}=\frac{a}{a'}$. With $N=10^9$, $r=3·09\ 10^{16}$ kms.;

and a (the sun's radius) $=7.10^5$ kms.; we had $a=3{\cdot}87.10^{-13}$. Hence $a'=7$ kms. gives $a'=3{\cdot}87.10^{-8}$; and $a''=1$cm. gives $a''=1/36{\cdot}9$. Hence if the whole mass of our supposed universe were reduced to globules of density 1·4 (being the sun's mean density), and of 2 cms. diameter, distributed uniformly through a sphere of $3{\cdot}09.10^{16}$ kms. radius, an eye at the centre of this sphere would lose only 1/36·9 of the light of a luminary outside it! The smallness of this loss is easily understood when we consider that there is only one globule of 2 cms. diameter per 360,000,000 cubic kilometres of space, in our supposed universe reduced to globules of 2 cms. diameter. Contrast with the total eclipse of the sun by a natural cloud of water spherules, or by the cloud of smoke from the funnel of a steamer.

Let now all the matter in our supposed universe be reduced to atoms (literally brought back to its probable earliest condition). Through a sphere of radius r let atoms be distributed uniformly in respect to gravitational quality. It is to be understood that the condition "uniformly" is fulfilled if equivoluminal globular or cubic portions, small in comparison with the whole sphere, but large enough to contain large numbers of the atoms, contain equal total masses, reckoned gravitationally, whether the atoms themselves are of equal or unequal masses, or of similar or dissimilar chemical qualities. As long as this condition is fulfilled, each atom experiences very approximately the same force as if the whole matter were infinitely fine-grained, that is to say, utterly homogeneous.

Let us therefore begin with a uniform sphere of matter of density ρ, gravitational reckoning, with no mutual forces except gravitation between its parts, given with every part at rest at the initial instant; and let it be required to find the subsequent motion. Imagining the whole divided into infinitely thin concentric spherical shells, we see that every one of them falls inwards, as if attracted by the whole mass within it collected at the centre. Hence our problem is reduced to the well-known students' exercise of finding the rectilinear motion of a particle attracted according the inverse square of the distance from a fixed point. Let x_0 be the initial distance, $\frac{4\pi\rho}{3}x_0^3$ the attracting mass, v and x the velocity and distance from the centre at time t. The solution of the problem, for the time during which the particle is falling towards the centre is

$$\tfrac{1}{2}v^2 = \frac{4\pi\rho}{3}x_0^3\left(\frac{1}{x}-\frac{1}{x_0}\right),$$

and

$$t=\sqrt{\frac{3}{8\pi\rho}}\left(\frac{\pi}{2}-\theta+\tfrac{1}{2}\sin 2\theta\right)=\frac{\pi}{2}\sqrt{\frac{3}{8\pi\rho}}\left[1-\frac{2\theta}{\pi}\left(1-\frac{\sin 2\theta}{2\theta}\right)\right],$$

where θ denotes the acute angle whose sine is $\sqrt{\frac{x}{x_0}}$.

This shows that the time of falling through any proportion of the initial distance is the same whatever be the initial distance; and that the time (which we shall denote by T) of falling to the centre is $\frac{1}{2}\pi\sqrt{\frac{3}{8\pi\rho}}$. Hence in our problem of homogeneous gravitational matter given at rest within a spherical surface and left to fall inwards, the augmenting density remains homogeneous; and the time of shrinkage to any stated proportion of the initial radius is inversely as the square root of the density.

To apply this result to the supposed spherical universe of radius $3{\cdot}09.10^{16}$ kilometres, and mass equal to a thousand million times the mass of our sun, we find the gravitational attraction on a body at its surface gives acceleration of $1{\cdot}37.10^{-13}$ kms. per second per second This therefore is the value of $\frac{4\pi\rho}{3}x_0$, with one second as the unit of time and one kilometre as the unit of distance; and we find $T=52{\cdot}8.10^{13}$ seconds $=16{\cdot}8$ million years. Thus our formulas become

$$\tfrac{1}{2}v^2=1{\cdot}37.10^{-13}x_0\left(\frac{x_0}{x}-1\right),$$

giving

$$v=5{\cdot}23.10^{-7}\sqrt{x_0\left(\frac{x_0}{x}-1\right)};$$

and

$$t=52{\cdot}8.10^{13}\left[1-\frac{2\theta}{\pi}\left(1-\frac{\sin 2\theta}{2\theta}\right)\right];$$

whence, when $\sin\theta$ is very small,

$$t=52{\cdot}8.10^{13}\left(1-\frac{4\theta^3}{3\pi}\right).$$

Let now for example $x_0=3{\cdot}09.10^{16}$ kms., and $\frac{x_0}{x}=10^7$; and therefore $\sin\theta=\theta=3{\cdot}16.10^{-4}$; whence $v=291{,}000$ kms. per second, and $t=T-7080$ seconds $=T-2$ hours approximately.

By these results it is most interesting to know that our supposed sphere of perfectly compressible fluid, beginning at rest with density $1{\cdot}61.10^{-23}$ of that of water, and of any magnitude large or small, and left unclogged by ether to shrink under the influence of mutual gravitation of its parts, would take nearly seventeen million years to reach ·0161 of the density of water, and about two hours longer to shrink to infinite density at its centre. It is interesting also to know that if the initial radius is $3{\cdot}09.10^{16}$ kilometres the inward velocity of the surface is 291,000 kilometres per second at the instant when its radius is $3{\cdot}09.10^{9}$ and its density ·0161 of that of water. If now, instead of an ideal compressible fluid, we go back to atoms of ordinary matter of all kinds as the primitive occupants of our sphere of $3{\cdot}09.10^{16}$ kms. radius, all these conclusions, provided all the velocities are less than the velocity of light, would still hold; notwithstanding the ether occupying the space through which the atoms move. This would, I believe,[1] exercise no resistance whatever to uniform motion of an atom through it; but it would certainly add quasi inertia to the intrinsic Newtonian inertia of the atom itself moving through ideal space void of ether; which, according to the Newtonian law, would be exactly in proportion to the amount of its gravitational quality. The additional quasi inertia must be exceedingly small in comparison with the Newtonian inertia, as is demonstrated by the Newtonian proofs, including that founded on Kepler's laws for the groups of atoms constituting the planets, and movable bodies experimented on at the earth's surface.

In one thousand seconds of time after the density ·0161 of the density of water is reached, the inward surface velocity would be 305,000 kilometres per second, or greater than the velocity of light; and the whole surface of our condensing globe of gas or vapour or crowd of atoms would begin to glow, shedding light inwards and outwards. All this is absolutely realistic except the assumption of uniform distribution through a sphere of the enormous radius of $3{\cdot}09.10^{16}$ kilometres, which we adopted temporarily for purposes of illustration. The enormously great velocity (291,000 kms. per second) and rate of acceleration (13·7 kms. per second per second) of the boundary inwards, which we found at the instant of density ·0161 of that of water, are due to greatness of the primitive radius and the uniformity of density in the primitive distribution.

To come to reality according to the most probable judgment present knowledge allows us to form, suppose at many millions, or thousands of millions, or millions of millions of years ago, all the matter in the universe to

[1] "On the Motion produced in an Infinite Elastic Solid by the Motion through the Space occupied by it of a Body acting on it only by Attraction or Repulsion." Cong. International de Physique, Paris, Vol. of Report. (*Phil. Mag.* August, 1900).

have been atoms very nearly at rest[1] or quite at rest; more densely distributed in some places than in others, of infinitely small average density through the whole of infinite space. In regions where the density was then greater than in neighbouring regions, the density would become greater still; in places of less density, the density will become less; and large regions will quickly become void or nearly void of atoms. These large void regions would extend so as to completely surround regions of greater density. In some part or parts of each cluster of atoms thus isolated, condensation would go on by motions in all directions not generally convergent to points, and with no perceptible mutual influence between the atoms until the density becomes something like 10^{-6} of our ordinary atmospheric density, when mutual influence by collisions would begin to become practically effective. Each collision would give rise to a train of waves in ether. These waves would carry away energy, spreading it out through the void ether of infinite space. The loss of energy thus taken away from the atoms would reduce large condensing clusters to the condition of gas in equilibrium[2] under the influence of its own gravity only, or rotating like our sun or moving at moderate speeds as in spiral nebulas, &c. Gravitational condensation would at first produce rise of temperature, followed later by cooling and ultimately freezing, giving solid bodies, collisions between which will produce meteoric stones such as we see them. We cannot regard as probable that these lumps of broken-looking solid matter (something like the broken stones used on our macadamised roads) are primitive forms in which matter was created. Hence we are forced in this twentieth century to views regarding the atomic origin of all things closely resembling those presented by Democritus, Epicurus, and their majestic Roman poetic expositor, Lucretius.

THE CHEMISTRY OF THE CYGNIAN STARS AND BASIC ROCKS.

I HAVE recently received from Prof. Suess the following important letter, with a request that it should be sent for publication in NATURE. It is obvious that Prof. Suess' striking generalisation will lead to many interesting inquiries; for my part I shall lose no time in making the additional researches for which he asks. The results on the chromosphere spectrum obtained during the eclipse of 1898 now being published by the Royal Society will also, I think, throw some light on the question. NORMAN LOCKYER.

Vienna, October 7.

MY DEAR SIR,—In reading your highly suggestive and instructive book on Inorganic Evolution and your last papers in *Proc.* Roy. Soc. and NATURE, I was struck by what you say on the spectrum of *a* Cygni, and beg leave to submit a question.

I believe I am in accord with the best masters of geology of our time in regarding our earth as a ball of NiFe, surrounded by a silicious slag. This slag has parted (or has differentiated) into two zones, one richer in SiAl and felspathic minerals (trachyte, granite, &c.), and the other richer in SiMg (peridotite and serpentine, olivine-rock, lherzolite, dunite, kyschtymite, &c.), and both extremes are united by a host of intermediate rocks. The SiAl group is lighter, exterior and partly used up in forming sediments, the SiMg group is lower or interior and related by the universal occurrence of traces of Ni, and by other features, to NiFe. They are, in fact, the acid and the basic group of Bunsen, Durocher and all their followers.

[1] "On Mechanical Antecedents of Motion, Heat and Light"; Brit. Assoc. Rep., part ii. 1854; *Edin. New Phil. Jour.* i. 1855; *Comptes rendus*, xl. 1855; Kelvin's "Collected Math. and Phys. Papers," vol. ii. art. lxix.

[2] Homer Lane, *American Journal of Science*, 1870, p. 57; Sir W. Thomson, *Phil. Mag.*, March 1887, p. 287.

Now Prof. Vogt, of Christiania, has in a series of remarkable papers shown that the metallic ores accompanying the SiAl rocks are different from the ores of the SiMg group, and that certain metals are very characteristic for each group, and more especially for certain ultra-basic rocks. The same author has, in *Zeitschrift für prakt. Geolog.*, 1898, p. 326, given a list of the elements characteristic for the ores of each group. This list does not regard the rocks themselves, but only the ores, and I have thought to give a better approach to the sum of occurring elements by introducing a few trifling changes, viz. in noting Si, Al and also Cu on both sides, and adding C, according to South African experience, to the basic list.

(1) Acid rocks: *Si*, *K*, *Li*, Be, *Al*, *W*, *U*, *Ce*, *Y*, Cu, *Sn*, *Zr*, *Th*, B, F.

(2) Basic rocks: Si, *Ca*, Al, Ba, Sr, *Mg*, *Fe*, Mn, *Ni*, *Co*, *Cr*, *Cu*, V, *Ti*, *Pt* and allied metals, *C*, P, *S*, Cl.

(The most characteristic members are italicised.)

The ultra-basic rocks have their exact equivalent in the meteoric stone of Chassigny.

The great number of analyses of meteor irons by Cohen recently published by the Berlin Academy gives Fe, Ni, Co, Cr, Cu, C, P, S, Cl, joined in single cases by SiO_2, MgO and CaO. You know that Davison also found Pt and probably Ir. It is Vogt's list of metals from basic rocks.

Ångström's older list of Fraunhofer lines gives H and Na, and besides these Ca, Ba, Mg, Fe, Mn, Ni, Co, Cr and Ti.

These are all elements accompanying the basic rocks, and although your own later observations show the existence of lines of some of the characteristic metals of the acid series, such as K, Li, U and Ce, I must conclude that Vogt's basic list is more distinctly represented in the sun's absorbing layer.

Now your comparison of the sun's chromosphere with the enhanced lines of *a* Cygni gives a quite similar list for *a* Cygni: Mg, Ca, Fe, Ti, Mn, Ni, Cr, V, Cu, Sr, and the impression is that the metallic vapours, which accompanied the intrusion of ultra-basic rocks and sometimes, as in Norway, gathered as ores at the circumference of these ultra-basic intrusive rocks, must have been of a remarkable likeness to those of the sun's chromosphere and of *a* Cygni.

One might even be induced to go a step further. Among the ores of the ultra-basic rocks Vogt distinguishes two varieties, which he calls the oxydic, characterised by the prevalent occurrence of Ti, and the sulfidic ores (nickeliferous pyrrhotite). And I find that you remark γ Cygni to be distinguished by the prevalence of Ti, *a* Cygni by Fe, Cr and Ni, and β Orionis by Si and Mg—corresponding to these two varieties of ores and to the intrusive rock SiMg (β Orionis being the country rock of the ores). But I am very far from proposing any conclusions whatever in this imperfect state of knowledge, and only venture to point out the interest which is attached to the examination of a number of elements named by you on p. 58, "Inorganic Evolution"—which have only been investigated by you with lower dispersion, and which embrace several typical representatives of the acid series—and to the special research of metals like W, U, Ce, Sn and others of this series.

The question, which I take leave to submit, is: Have we indeed to suppose that metallic vapours answering to metals from acid rocks are less represented in the sun and stars than those from basic rocks, or is it some secondary cause, the nature of their spectrum or other, which gives the present seeming prevalence to the metals from basic rocks?

I beg you, dear sir, to accept the expression of my highest esteem.

Yours most respectfully,

EDW. SUESS.

RUDOLPH KOENIG.

THERE has passed away in the person of Dr. Rudolph Koenig one whose name will be remembered in the science of physics, and who filled a unique place. To the outer world he was known simply as a maker of tuning-forks. To the inner circle of science he was known as the author of original researches in a line peculiarly his own. To the few who had the privilege of an intimate acquaintance he was known as a simple-hearted, whole-souled devotee of his chosen science of acoustics: one who lived for and loved his work.

Born at Königsberg in 1833 of a family connected with the University, he was himself trained in the Philosophical Faculty of that famous centre. He graduated as Doctor of Philosophy, and well might have looked forward to a successful career as professor of physics in one of the Universities of his native land. What cross-currents of destiny drove him far afield are not clearly known to the present writer. But the year 1860 saw him established in Paris as a constructor of acoustical instruments, carrying out the traditions of fine workmanship established by Cavaillé-Coll. He had an *atélier* in the Place du Lycée Louis le Grand, and here he worked out a number of new acoustical instruments. The phonograph, or phonautograph as it was later called, of M. Scott de Martinville for recording the vibrations of tones and words was brought to Koenig to be put into shape. Accounts of this instrument will be found in *Cosmos*, vol. xiv., in the *Athenaeum* of 1859, and in the Report of the British Association for the same year. It was Koenig's part to devise a better mouthpiece and a more sensitive membrane. He also devised the recording drum, driven on an axis cut with a screw thread. I once asked him whether, when he was working with M. Scott on this instrument, it had not occurred to either of them that the record of the vibrations might not be used over again to reproduce the sound, as discovered nearly twenty years afterwards by Edison. His reply was: "No, the idea never occurred to either of us; we never thought of anything except recording." He constructed series of standard tuning-forks furnished with recording styluses; he improved the mechanical construction of the Seebeck siren; he studied the vibrations of plates and of columns of air. In 1862 he brought over to London to the second of the series of International Exhibitions a fine set of his new apparatus, including an acoustical album or collection of graphic tracings recording the composition of vibrations; and for the exhibit he was awarded a gold medal. About the same time began the publication of his experimental researches in acoustics which lasted nearly forty years. The earliest of these to be noted was the invention of the manometric flame. Organ pipes fitted with manometric capsules for investigating the vibrations of the air column by means of gas-flames were shown in the London Exhibition of 1862, and they were described by him in vol. cxxii. of Poggendorff's *Annalen*, pp. 242 and 246, of the same year. He constructed resonators for Helmholtz (see Appendix I. of the first edition of the "Tonempfindungen," 1863); he repeated the experiments of Philipp Reis with the primitive telephone of that neglected inventor; he devised a new stethoscope furnished with one or more flexible rubber tubes to admit of simultaneous auscultation by several observers. In the *Comptes rendus* of March 1864 he had a memoir upon the vibration of plates, in which he discussed the sound-figures in sand discovered by Chladni and the explanation of their formation then recently suggested by Wheatstone. In 1870 he had another article in the *Comptes rendus*, on the fixed notes which are characteristic of the different vowels. In 1872 came a second memoir on manometric flames in the *Annalen*.

During these ten years Koenig had been attempting to build up the business of manufacturer of acoustical instruments. His standard tuning-forks were sought after by physical investigators. The impulse given to acoustical subjects by the publication of the famous book of Helmholtz was undoubtedly great; and the researches of Chladni, Wertheim, Melde, Terquem, Wheatstone and Mach were claiming great attention. Koenig adopted the suggestion, urged by Chladni in 1830, of fixing as the normal scientific pitch for his standards that in which middle C of the keyboard is assigned to 256 complete vibrations per second. In the "Catalogue of Acoustical Apparatus" which Koenig published in 1865—itself an evidence of his scientific and industrial activities—he notified his adherence to this standard for the *diapason normal*. He had now moved into the Rue Hautefeuille on the south side of the Seine, where he lived and worked until about 1878, when the house was demolished in the construction of the Boulevard St. Germain through the Quartier Latin. Unhappily the outbreak of the Franco-Prussian War rendered it difficult for a German to live in Paris. Of a retiring and sensitive disposition, he found himself somewhat isolated in his work. The scientific world was rather cold toward the man who made a living out of selling tuning-forks. Other instrument makers began to copy his instruments, and were able, not having the same scientific ideals, to undersell his manufactures by producing less carefully-made articles. Koenig never swerved one hair's breadth to meet this competition. He knew the quality of the work that left his little factory. Not one tuning-fork, during these more than thirty years, left the place without having been personally adjusted and verified by him. No single instrument of second quality ever bore his mark. The monogram "R. K." stamped upon his work became an absolute guarantee of first-rate workmanship. Others might cheapen their manufacture by neglect of quality: he would maintain the quality of his *coute que coute*. If by some stroke of luck he sold instruments that brought in a few hundred francs above the regular income of his business he would hail it as the means of constructing some new piece of experimental apparatus that might never find a sale, but would help his investigations. And so with a slender business and a few faithful workmen at his back he maintained a proud independence, sufficient to enable him to continue research.

In 1876 he went over to America and took with him to the Centennial Exposition at Philadelphia a splendid series of his beautiful instruments in the hope of doing advantageous business. The Jury's report of the awards in Group xxv. speaks in glowing terms of this effort. "In the present Exhibition," it runs, "Dr. Koenig has presented a collection of instruments of demonstration and investigation constructed on a scale of magnitude heretofore unattempted, and exhibiting with surprising power the effects of interfering undulations. He also presents a tonometric apparatus, consisting of about 670 diapasons or tuning forks, giving as many different shades of pitch, extending over four complete octaves, and making equal intervals of eight simple vibrations each for the first octave, and of twelve each for the succeeding octaves; the whole forming an absolutely perfect means of testing, by count of beats, the number of vibrations producing any given musical sound, and of accurately tuning any musical instrument. In addition to these more conspicuous portions of his display, Dr. Koenig exhibits the various forms of apparatus of demonstration for which he is so well known, all of which are marked by the accuracy of indications and excellence of workmanship which have given him his deserved reputation as a constructor." . . . "Of the exhibit of Dr. Koenig, as a whole, it may be said that there is no other in the present International Exhibition which surpasses it in scientific interest." The interest excited by this exhibit was so great that an appeal was circulated, signed by Joseph Henry and others, suggesting the purchase of the instruments. Koenig was induced to leave them at the University of Pennsylvania under promise of their being insured for 10,500 dollars and of a weekly account of the subscription being sent to him. But after a long and vain expectation of the weekly accounts, and the writing of many unanswered letters, it became evident to Koenig that things were going wrong. In June 1878 Mr. Munzinger, who had undertaken to collect the funds, announced to Koenig that he had remitted the whole subscription to Prof. Barker, but on December 15, 1879, Prof. Barker wrote: "Mr. M. has not yet turned over to me the subscription for the acoustical collection." On June 30, 1882, he again wrote: "With regard to your collection, I have been entirely unable to complete the subscription for its purchase." There remained nothing for Dr. Koenig to do but to go over and remove the collection. A portion of it was sold at some sacrifice to the University of Toronto, the physical collection of which it adorns; while the rest was brought back to Paris. The incident had the most unfortunate effect on Dr. Koenig. It crippled his slender resources for more than ten years, and it tended to sour his sensitive temperament. He had in 1876 communicated to Poggendorff's *Annalen* two papers, one on a tuning-fork of variable pitch, the other upon the phenomena produced by the interference of two tones. This latter paper is one of the undoubted classics of science. Using the most splendid and perfect of all tone-producers, the substantial steel tuning-forks of his own design, he had for years been investigating the phenomena of beats and the production of interference-tones. Applying the phenomena of beats every day in his workshop for the purpose of adjusting forks to their exact pitch, he acquired a familiarity with the phenomena such as no other experimenter could possibly attain. His published research is a model of careful and accurate observation. Helmholtz had given the well-known theory that when two tones are sounded together there are produced two other tones, known as the difference-tone and the summation-tone, having frequencies respectively corresponding to the difference and the sum of the frequencies of the two fundamental tones. Koenig, finding himself unable to confirm the existence of these alleged tones, set to work to find out what the actual facts were. He investigated both the beats and the resultant tones. He found that primary beats were not all of one kind; that they could be ranged in two sets, an inferior and a superior set. Of these the inferior alone correspond to the difference of the frequencies, and so correspond only in the first octave. Outside the first octave neither set of beats corresponds either to difference or to sum. He found that when with higher forks resultant tones are produced they likewise may be ranged in two sets, an inferior and a superior set, the pitch of these resultant tones being always precisely that calculated as for beats. These resultant tones are never either summation-tones or difference tones except for tones within the range of the lower half of the first octave of relative pitch, within which limits alone they correspond to the difference of the frequencies. Outside that limit there are no difference-tones. Under no circumstance, when pure notes are used as the two fundamentals is the alleged summation-tone heard. It is true that Prof. Rücker has by the most refined optical appliances demonstrated the objective existence of the summation-tone. But the source was a powerful siren which notoriously generates an impure tone. Koenig's statement of 1882, "Je ne connais jusqu'à present aucune expérience par laquelle on pourrait prouver avec quelque certitude l'existence de sons différentiels et de sons d'addition," remains absolutely true to-day. During the years that followed the unhappy incident of 1876 Koenig continued his investigations. Amongst the apparatus at Philadelphia was the first of his wave-sirens, a novel instrument which for the first time enabled the experimenter to build up synthetically a complex tone out of harmonic constituents in such a way as to vary at pleasure the phases of the component tones. He had discovered that, contrary to the theory of Helmholtz, phase-difference does exercise a modifying effect upon the timbre, and is physiologically observable. This theme he developed in a memoir entitled "Bemerkungen über die Klangfarbe," which was published in *Wiedemann's Annalen*, vol. xiv., in 1881. For this research he constructed a large new wave-siren on a different plan. The same instrument enabled him to investigate the properties of tones produced by a succession of irregular waves. In 1882 he published, under the title of "Quelques Expériences d'Acoustique," a volume of 243 pages resuming his experimental researches down to that date. This volume is now very scarce: it is a veritable treasury of careful and refined experimental investigation. Of these acoustical researches a summary was given by the present writer in NATURE some years ago. In 1890 Dr. Koenig brought over to London his large wave-siren and a number of the larger tuning-forks, and himself demonstrated the principal points of his researches before a meeting of the Physical Society. These instruments were also shown at the Royal Institution in June of the same year at a Friday evening discourse on the physical basis of music. A few of the forks were acquired for the National Collection at South Kensington.

On recovering in the autumn of 1882 the unsold portion of his acoustical collection, he proceeded to reconstruct, on a larger scale than before, the great tonometer, the series of standard tuning-forks which originally extended in unbroken series only from the frequency of 128 to that of 4096 vibrations. He added massive steel forks, some of them weighing nearly 200 pounds, taking the frequency down to 16, while at the higher end of the scale he added several octaves, so that eventually he reached a pitch above the superior limits of ordinary audition. One of his latest researches was, indeed, upon the verification by the method of Kundt of the wave-length of these inaudible forks, going up to 45,000 vibrations per second. This splendid set of standard instruments has remained until now in Dr. Koenig's *atélier*. An attempt was made about three years ago—unfortunately without success—to secure it for the National Collection of Scientific Apparatus at Kensington. It can never be duplicated, and its dispersal would be a misfortune for science.

Dr. Koenig suffered during his last years from much broken health. He never married, but lived alone, surrounded by the instruments of his creation, in his workshop on the Quai d'Anjou. Here he received from time to time the visits of his friends. The late Mr. Spottiswoode used frequently when passing through Paris to visit him. A brief word of announcement that one would give oneself the pleasure of calling next Sunday morning always found Koenig ready and pleased to spend an hour in showing his latest experiments. The last time that I had this opportunity was during the Electrical Congress in September 1900. He had during the preceding week had a similar visit from Lord Kelvin. Koenig was even then very ill. He suffered terribly in body and was obviously feeble. For some months he had lived on nothing but milk. But he was as animated and keen as ever. He had some new observations and a new instrument—no account of which has been published—demonstrating the influence of phase upon the quality of compound tones. They were simple and convincing. But the occasion was mournful; his bodily sufferings were only too evident. He wrote me in the spring of the present year that his health was still more precarious. He died on October 2, 1901, aged sixty-eight years.

Dr. Koenig was an honorary fellow of the Physical Society of London. He had received few tokens of recognition from academies or learned societies; and this one, conferred only last February, gave him evident pleasure. But his work, so courageously maintained in the true spirit of scientific devotion, will remain as his monument to all time. S. P. T.

THE McCLEAN TELESCOPE AT THE CAPE OBSERVATORY.

WE have on many occasions recorded munificent gifts towards scientific research and education from wealthy Americans and others, and now and again it has been our pleasurable duty to call attention to instances of similar generosity on the part of our own countrymen. Naturally it is more gratifying for us to record the latter than the former, especially, perhaps, as the occasions are less frequent. The weekly edition of the *Cape Argus* for October 2 instances a notable example of such a gift in its account of the ceremony which took place recently of the unveiling, by his Excellency the Governor (Sir W. Hely-Hutchinson), of the inscription stone of the magnificent telescope which Dr. Frank McClean, F.R.S., has presented to the Royal Observatory at the Cape. This telescope was offered and accepted some years ago, but many delays have occurred.

Says our contemporary: "The pleasant little ceremony . . . deserves more than passing mention. It gives an opportunity for the cultivation of a virtue which is not too common at the Cape—the virtue of gratitude which Shakespeare knew as a 'noble thankfulness.' And if for the nonce the public should be led to depart from its usual Philistine attitude towards pure science and the higher walks of research, the change may not be ungraceful, and may do it good. The value of Mr. McClean's gift it would be hard to overestimate. In mere money's worth it was princely—more than the Imperial Government could well spare, and more than the Colonial Government could venture to dream of as an encouragement to unapplied science. It was given, too, at the right time and to the right place, there being immediate need for a wide development of spectroscopic work, and the southern hemisphere being poorly supplied with astronomical equipment compared with the affluent north. Further, it did not come from a mere millionaire, willing to be moderately fleeced in return for a little notoriety; Mr. McClean was a skilled and assiduous worker in this branch of science, and what he gave was the outcome of a pure heart and a noble enthusiasm. Nor did he stop at the purely material gift, but gave time and thought and trouble to make sure that the telescope and its accompaniments should be fit for the performance of the very best type of work. He came to the Cape and resided for months here, and those who were privileged to meet him will always remember his unassuming ways and his unflagging interest in his work. He had a double purpose in coming, and by far the greater portion of his time was spent in obtaining the spectra of certain southern stars, in order to supplement his similar work in the north. When this was done, the kindly English gentleman left as quietly as he came. The scientific equipment of the Colony had been handsomely enriched by him, but so far as the general public was concerned he left 'unhonoured and unsung.' . . . The need of scientific and literary endowments at the Cape is well known, and the forgetfulness of those whom the land has made wealthy is occasionally bewailed: it would ill become us, therefore, to be equally forgetful of the far-seeing liberality of a stranger who owed us nothing."

The proceedings were opened, in the presence of a distinguished company, by Sir David Gill, K.C.B., F.R.S., His Majesty's Astronomer at the Cape, who delivered an address, space for which we regret to be unable to spare, after which Sir W. Hely-Hutchinson, in the course of a brief speech, said that in regard to the magnificent gift which Mr. McClean had made to the Observatory, he ought to say that it was the desire of H.R.H. the Duke of Cornwall and York to have performed the ceremony which he (the Governor) was now inadequately to undertake. The fact that the telescope had been named the "Victoria Telescope" was, doubtless, one reason which had actuated His Royal Highness in this regard, but the fact that so handsome—he might say, so princely—a gift had been made to science deserved the full recognition of the highest in the land. His Royal Highness not having been able, however, to unveil the inscription stone, owing to the great number of engagements which were pressed upon him during his recent visit, it had fallen to his (the Governor's) part to do so.

The whole company then proceeded to the outside of the building, where his Excellency removed the Union Jack which covered the inscription stone. The inscription was simply as follows:

1897: The Victoria Telescope.
The Gift of Frank McClean,
of Rusthall, Kent.
David Gill, H.M. Astronomer.

While assembled round the stone cheers were given, first for the donor of the telescope and then for the Governor, and the proceedings terminated.

THE NERNST LAMP IN AMERICA.

THE paper read last August by Mr. A. J. Wurts at the annual convention of the American Institute of Electrical Engineers on the development of the Nernst lamp in America is especially interesting as being practically the first to contain any full description of the physical characteristics of the Nernst filament, or "glower" as it is generally called to distinguish it from the carbon filaments of incandescent lamps. It is interesting, too, in that it affords evidence that the lamp is eventually emerging from the laboratory stage and becoming a really trustworthy commercial article. It will be remembered that shortly after Nernst's invention was made public the commercial development of the lamp was taken up by four companies—by the Allgemeine Elektricitäts Gesellschaft in Germany, by the Westinghouse Company in America, by the Nernst Electric Light in England and by Ganz and Co. in Austria. The German company, who possess the patent rights for most of Europe, including England, have for some time had the lamp on the market in Germany, and, as their exhibit at the Glasgow Exhibition shows, are now introducing it into this country. The Westinghouse Company have also, to judge by the paper by Mr. Wurts, developed the lamp to a degree justifying its introduction into commercial use in America. Three or four years may seem to some a long time to have spent on the improvement of Nernst's invention before it could be considered practically available, but when the great complexity of the lamp as compared with an ordinary incandescent lamp is taken into account it cannot be regarded as excessive.

We propose to consider briefly some of the electrical properties of the glower as described by Mr. Wurts rather than to give a detailed account of the mechanical construction of the lamp. Those who take an interest in this side of the subject may be referred to the *Electrical Review* of New York for August 31 and September 7, in which will be found a full reprint of the paper and a short summary of the discussion which it raised. The glower, as is well known, is made of a mixture of oxides similar to those used in the manufacture of Welsbach mantles, which are mixed to a paste and then pressed through a die into threads of the desired thickness. These threads are cut into convenient lengths and baked, after which leading-in wires are affixed to the ends. This connection, as originally made by Dr. Nernst, consisted of a few turns of platinum wire twisted round the ends of the glower and cemented to it by a suitable paste; the terminal connection worked out by the Westinghouse Company has the platinum lead wire terminating in a small bead which is actually embedded in the end of the glower, the object being to prevent any shrinking of the glower spoiling the contact between it and the platinum. It has often been stated that if the current through a glower be altered, the potential difference between its ends falls as the current is increased. The curves published by Mr. Wurts show that for a glower burning in air this statement is not quite correct; the curves only give the characteristic of the glower between 0·3 and 0·65 ampere, but they show that as the current is increased from 0·3 to 0·5 ampere the potential difference rises also, from 180 to 197 volts; the potential difference remains constant as the current is further increased up to 0·55 ampere, after which it begins to fall slightly. It is, however, quite evident that if the glower is run anywhere near the crest of this curve, as is the case in practice, a steadying series resistance is essential, especially on a circuit in which the voltage fluctuates, as it does on all the supply circuits with which we are acquainted.

In the above respect the glower behaves in a manner comparable with the arc rather than with the carbon filament. The behaviour is generally accounted for by saying that the glower being an electrolytic conductor becomes less resisting as its temperature is increased. That the phenomenon is, however, more complex than this is shown by the characteristics of the glower in other gases than air, or in a vacuum. For a glower burning in oxygen the characteristic appears to be almost identical with the air curve; when nitrogen is used the curve is similar in shape, but the maximum voltage occurs at a lower current and is about 4 per cent. less in magnitude. The characteristics for hydrogen and a vacuum show only a falling curve; there is no portion within the same current limits in which the potential difference rises with the current. These results seem to indicate that some chemical changes are going on between the glower and its surrounding envelope of gas which have an important influence on its behaviour and very possibly on its efficiency and life. There can be little doubt that when the Nernst lamp is easily available it will open up a field of research as interesting and possibly as fruitful as that afforded by the electric arc.

The work of M. Blondel and Mrs. Ayrton has made us familiar with the physical necessity of a resistance in series with the arc on account of its falling characteristic. Such a resistance is still more necessary with the Nernst glower—since a smaller overload of current is more dangerous. With an arc a comparatively small "dead" resistance in series is sufficient, that is to say a resistance which remains of practically constant value throughout the working range of current and does not heat sufficiently with a small overload to alter appreciably. But with the glower it is easy to see, from the curves published by Mr. Wurts, that if a dead resistance were used it would have to be so large for safety as to greatly diminish the efficiency of the complete lamp. A resistance has therefore had to be sought which will increase very rapidly with increase of current, and the solution of the difficulty has been found in using fine iron wire nearly at a red heat, the wire being enclosed in a small sealed bulb filled with hydrogen to prevent its oxidation. This "ballast," as it is named by the Westinghouse Company, has a remarkably high corrective power; with a rise in current of 15 per cent. the resistance increases about 180 per cent., the potential difference between its terminals increasing 200 per cent. As a consequence with such a ballast in series with the glower, a rise in the supply pressure does not produce a serious increase in the current. It follows also that the Nernst lamp (consisting of glower and ballast) cannot be overrun in the same way as an incandescent lamp in order to get it to give more than its rated candle-power or to work at a higher efficiency. With an increase of the supply pressure of 5 per cent. the candle-power of an incandescent lamp increases 40 per cent., whereas that of the Nernst lamp only rises about 7 per cent., the corresponding increase in efficiency being 26 per cent. and 2 per cent. respectively. It is obvious that as this result is attained by running the iron wire nearly at a red heat, the resistance of the ballast when cold is considerably lower than its correct working resistance, and there is therefore a tendency for the glower to take too much current when it first lights up. The ballast has for this reason to be constructed in such a way that the iron wire shall very quickly assume its full resistance, a requisite satisfied by the free suspension of the wire in the hydrogen bulb.

Mr. Wurts does not give any curves showing the candle-power and efficiency during the life of the glower, a thing to be regretted, as it is by the performance of the lamp in this respect that it must ultimately stand or fall. It is, however, stated that the average life of 220-volt glowers on a by no means over steady alternating circuit was found to be from 800 to 900 hours, and that neither the efficiency nor the candle-power fell off much during this life. The life of the 110-volt glowers is said not to be so good, and the average life of the glowers on direct current is given as only about 250 to 300 hours. It should not be assumed that this is an inherent defect, as the Westinghouse Company have devoted their attention mainly to alternating current, and since the German company make lamps for either type of supply it seems evident that the difficulty can be overcome.

We have done no more than indicate a few of the many interesting considerations raised by Mr. Wurts' paper; it contains in addition descriptions of the heater, of the cut-out used for breaking the heater circuit when the glower lights, and of the complete lamp as now constructed in America. Suffice it to say that the lamps are made in candle-powers from 50 to 2000, the higher candle-powers being obtained, not by the use of a larger glower, but by mounting a number of glowers in parallel in the same lamp. Smaller candle-powers than 50 have not been made, as it has been deemed advisable to design the lamp to compete with the arc rather than with the incandescent lamp. In conclusion, we must agree with Mr. Steinmetz, the president of the American Institute, that the lamp should not be compared too severely with existing standardised lamps since, as it is just fresh from the laboratory, it is to its promise rather than to its performance that one should look. And there can be little question but that its promise is exceptionally good.

FLORAS OF THE PAST.[1]

THIS "extract" from the twentieth annual report of the U.S. Geological Survey forms a bulky volume of more than 200 pages and 150 plates. Prof. Lester Ward tells us in the introductory remarks that the aim of the memoir is "to give a succinct account of the progress thus far made in the direction of developing the Mesozoic floras of the United States." The present instalment deals with the vegetation of the Triassic and Jurassic

[1] "Status of the Mesozoic Floras of the United States." First Paper: The Older Mesozoic. By Lester F. Ward, with the collaboration of W. M. Fontaine, A. Warner and F. H. Knowlton. Pp. 211–430 + Plates xxi–clxxix. (Washington: Government Printing Office, 1900.)

periods, the Cretaceous floras being reserved for a second part. The numerous scattered references to the Mesozoic botany of the United States, and the conflicting opinions that have been expressed as to the geological age of the plant-bearing beds, enable us to thoroughly appreciate the value of a comprehensive report compiled by one who possesses a wide knowledge of palæobotanical literature. It is, however, not solely with published facts that the volume is concerned, for a large portion of it is devoted to a systematic account of recently discovered species. The Triassic floras are represented by fossils from the Connecticut Valley, Pennsylvania, Maryland, Virginia and other regions, while plants of Jurassic age are described from California, Oregon and Wyoming. One of the chief desiderata from the point of view of palæobotanical research is a careful and critical examination of the records of ancient floras, which may be of use in the consideration of the broad problems connected with plant evolution and distribution. In the treatment of work of this kind it is essential to carefully weed out such material as cannot be determined with sufficient accuracy to furnish trustworthy evidence. This obvious reflection is suggested by a perusal of the numerous determinations and descriptions contained in the volume before us. It is unfortunate that the plants from the Jurassic strâta of California (the Oroville flora) are in most cases represented by fragmentary samples, and in several instances these have been referred to genera and species on evidence which cannot be accepted as satisfactory. Systematic work on fossil plants has too frequently been marred by a want of self-control on the part of authors who appear to be led away by a desire to attach names to specimens that are absolutely valueless as botanical records; we are compelled to add that the utility of the descriptive portions of this work is seriously impaired through lack of courage to discard worthless material. More than eighty specimens of cycadean stems are recorded from the Freezeout Hills of Wyoming—probably of Jurassic age. These stems are referred by Prof. Ward to a new genus, *Cycadella*, which is described as being characterised by the relatively small size of the trunks and by a dense covering of ramental tissue "exuberantly developed from the leaf-bases and extruded from the armour, massed and matted in the fossil state so as to form a thick outer covering." The exceptional development of the ramental scales suggests a comparison with the abundance of woolly hairs on the carpophylls of the recent cycadean genus *Dioon*, and constitutes an interesting feature which may serve as an index of climatal conditions.

The characters on which the cycadean stems are referred to distinct species are hardly such as to deserve specific recognition, and in looking over the numerous plates devoted to the specimens, one fails to appreciate the advantages gained by the reproduction of more than a hundred photographs, in most cases exhibiting only surface features which are often indistinctly shown and give little or no information of botanical value. Prof. Ward admits that the characters made use of in his classification are not the most satisfactory for diagnostic purposes, but we would urge that in the absence of more useful characteristics, such as might be obtained from an examination of the anatomy of the petrified stems, the application of specific names serves no useful purpose, but rather tends to confusion. Little information is given in regard to the reproductive organs; these are described as being less numerous than in other fossil cycads, but they appear to agree in position and in form with those of the *Bennettites* type.

There is no more striking feature of the Mesozoic vegetation of the United States than the extraordinary abundance of silicified cycadean stems, and no more valuable contribution could be made to our knowledge of extinct types than a comparative morphological account of the vegetative and reproductive organs of the American fossil cycadales. A foretaste of what may be expected has been supplied by Mr. Wieland, who has already published some descriptions of the reproductive organs of cycadean plants in the large collection at Newhaven; it is an extension of this kind of work that is urgently needed and for which there appears to be no lack of material.

Some pieces of coniferous wood are described by Mr. Knowlton and referred by him to *Araucarioxylon? obscurum*, n.sp., but in this case also the data are insufficient to justify the adoption of a distinctive specific name.

Apart from these criticisms as to the methods adopted in the systematic part of the work, we can cordially congratulate Prof. Ward on the completion of the first part of a research which must be of great value to students of palæobotany. A. C. S.

NOTES.

WE are glad to notice that the daily Press is endorsing what we have for years been endeavouring to bring home to the nation, viz. a better appreciation of the advantages of science and of scientific training. A notable instance of this is to be found in a leader in the *Times* of Monday last on the anniversary of Trafalgar, in the course of which our contemporary, in speaking of the recent naval disasters and breakdowns, says that these mishaps "suggest, if they do not indicate, some failure of competence, some lack of coordinating intelligence, among those who are responsible for the structural perfection of our warships. If this were so, it would tend to show that the national failing of which we have seen too many evidences of late, of neglect of scientific training, of the practical man's contempt for scientific method, of self-satisfied contentment with the traditional, the makeshift and the second best, is beginning to find its way into the constructive and engineering departments of the Admiralty." "We have heard much of late," remarks our contemporary, "about the need for 'standardising' our machines. Let us try if we cannot 'standardise' our educational methods and our intellectual equipment generally—not, indeed, according to the 'standards' of the Education Department, but according to the standard of the best that is known, and thought, and done in the world. In the Navy of to-day," says the *Times*, "there is zeal, capacity, energy and devotion in all respects worthy of the heroic past. The only thing that seems to be wanting is what is wanting in the nation, belief in knowledge and faith in applied intelligence." We trust that at this time, when we are being outstripped in many directions by foreign rivals, and commercial invasion has come to our very doors, and orders for machinery, railway locomotives, &c., are going in increasing numbers to our more energetic and receptive kinsmen across the sea, such words of warning as we have quoted will receive due attention and be acted upon ere it be too late.

THE question of fogs in London is at last, we are glad to see, to receive attention. The General Purposes Committee of the London County Council having had under consideration a letter from the secretary of the Meteorological Office, stating that it is proposed to hold an inquiry into the occurrence and distribution of fogs in the London district and their relation to other atmospheric and local conditions, and asking for the co-operation of the Council in the conduct of the inquiry, propose "(1) That a gentleman of suitable scientific qualifications be engaged by the Meteorological Council for a limited period, to formulate instructions and a scheme of observations, and to conduct the investigation; (2) that the observations be taken at the various Fire Brigade stations, and by men of the Fire Brigade; and also, if it can be so arranged, at other institutions of the London County Council; (3) that the returns be sent from the various stations, and from any other institutions selected, direct to the

Meteorological Office; (4) that the Meteorological Council do arrange with the police authorities for observations to be taken at selected positions outside the County of London; (5) that all responsibility as to the conduct of the investigation and any published results of such investigation do rest with the Meteorological Council; (6) that a copy of the complete returns and twelve copies of a report thereon by the Meteorological Council be supplied to the London County Council, and that the London County Council do contribute a sum of 250*l.* for the investigation." The steps about to be taken are most important, and should certainly lead to very valuable results.

THE second annual Huxley lecture of the Anthropological Institute will be delivered by Mr. Francis Galton, F.R.S., at the rooms of the Society of Arts, John Street, Adelphi, on the 29th inst., at 8.30 p.m. The subject chosen by the lecturer is "The Possible Improvement of the Human Breed under the Existing Conditions of Law and Sentiment." Tickets may be obtained on application at the Institute, 3, Hanover Square, W.

THE Frankland memorial lecture will be delivered before the Chemical Society by Prof. H. E. Armstrong, F.R.S., on Thursday next at 8.30 p.m.

THE opening meeting of the session of the Institution of Electrical Engineers for the presentation of premiums and the delivery of the presidential address will take place on Thursday, November 21, instead of on November 14 as was previously announced.

ARRANGEMENTS are being made for the next congress and exhibition of the Sanitary Institute to be held at Manchester in September, 1902. Earl Egerton of Tatton has accepted the presidentship, and the use of the Owens College buildings has been granted by the senate for the sectional meetings and as reception rooms. The exhibition will be held in the St. James's Hall.

THE eleventh Congress of Russian Naturalists and Medical Men will be held in St. Petersburg from January 2 to 12, 1902. There will be sections devoted to mathematics and mechanics, astronomy and geodesy, physics, physical geography, chemistry, geology and mineralogy, botany, zoology, anatomy and physiology, geography (with a subsection relating to statistics), medicine and hygiene, and agronomy.

THE next International Geographical Congress will be held in 1904 in Washington, under the auspices of the National Geographic Society, the president of the latter, Dr. Graham Bell, having just heard from Baron von Richthofen, president of the executive committee of the last Congress, of the acceptance of the invitation to Washington which had been tendered by the Society. In consequence of the decision of the executive, and in view of the coming Congress, the October issue of the *National Geographic Magazine* contains a brief account of the meetings of the Congress which have already taken place, and gives a list of possible excursions in America, each of which would be a geographical lesson.

THE new bacteriological department of the Royal Infirmary, Bristol, will be opened to-morrow by Sir Frederick Treves, K.C.V.O., who will afterwards distribute the prizes to the successful students in the Faculty of Medicine of University College, Bristol, and preside at the annual dinner of the Medical School.

PARIS was greatly excited on Saturday last when M. Santos Dumont, with his seventh balloon, successfully rounded the Eiffel Tower and returned to the shed at St. Cloud, thirty seconds within the thirty minutes allotted by the Committee of the Deutsch Prize. At the time of the voyage the wind, according to the *Times* correspondent, was blowing at the rate of twelve or thirteen miles an hour. At one period the balloon, travelling at the rate of thirty miles an hour, appeared as though it would collide with the Tower; the aëronaut, however, was able to control its movements without any apparent difficulty, and, as has been said, the journey was accomplished within the time limit agreed upon. M. Santos Dumont is to be congratulated upon the success which has at last attended the untiring efforts put forward by him towards the solution of the problem of aërial navigation.

THE death occurred last week, in his fifty-sixth year, of Dr. James Foulis, of Edinburgh. In 1872, at the suggestion of Prof. (now Sir William) Turner, he began to study the structure of the ovary and the development of the ova, more especially in reference to the then recently published work of Waldeyer. In 1874 the degree of M.D. and the gold medal for a thesis on this subject was conferred on him. The following year, having made many additional observations on the anatomy of the ovary, he contributed a paper to the Royal Society of Edinburgh on the development of the ova in man and other mammalia, which was published in the *Transactions* of the Society. Dr. Foulis published other papers, and in 1875 obtained the first award of the Prof. John Goodsir memorial prize for the encouragement of the study of anatomy and physiology.

WE regret to have to record the death of Canon Isaac Taylor, which took place on Friday last in his seventy-third year. Canon Taylor was the author of, among other works, "Words and Places," "Names and their Histories," "Etruscan Researches," "Greeks and Goths, a study in the Runes," and "The Alphabet, an account of the History and Development of Letters." He was one of the founders of the Alpine Club, and took great interest in gardening and entomology.

THE death is announced of Privy Councillor Maercker, professor of agricultural chemistry at the University of Halle.

AN interesting and valuable gift has just been made to the Ashmolean Natural History Society of Oxfordshire by Mr. Henry Willett, of Brighton, and consists of a piece of ground about five acres in extent, comprising woodland, marsh bog and water, which contains many local and rare specimens of animal and vegetable life. It is the wish of the donor that the land shall be known as "The Ruskin Plot," and that it shall be kept for all time in its natural condition. In order to ensure this a trust is being prepared which will vest the plot in the following trustees:—The Lord-Lieutenant of Oxfordshire, the Vice-Chancellor of the University, the Radcliffe Librarian, the Hope professor of zoology, the Sherardian professor of botany, and the donor. The ground in question is situated at Cothill, near Abingdon, Berks, and is meant more for observation than for collecting purposes. It is hoped that a systematic record, year by year, of a piece of ground untouched by cultivation will be of considerable interest.

AT this moment, when the metropolis is menaced by small-pox, the founding of a league which has for its objects the spread of a wider knowledge of the benefits derived from vaccination and a better understanding among the general public of the advantages arising from preventive medicine and practical sanitation, cannot but be deemed opportune. The Vaccination League has, we understand, the support of Mr. Jonathan Hutchinson, Sir Alfred Garrod, Prof. Charles Stewart and many other medical men.

A GREAT landslip has occurred in Barbados, of the extent, it is said, of 500 acres. The Boscobel district plantations and buildings have been wrecked, eighty-five houses have been swept into the sea, and 400 people are homeless. Roads have disappeared and all the landmarks are gone.

THE *Athenæum* gives the following particulars respecting the new meteorological station which has just been established at Achariach, in Glen Nevis. The situation is such that a spur of Ben Nevis shuts in the valley to the west, and the height above sea-level is only 165 feet. The intention of the founder of the station—Mr. R. C. Mossman, of Edinburgh—is "to study the thermal conditions in the valley and on the adjacent hillsides during anticyclones in winter." It seems that in calm, cold weather and with a high barometer it not seldom happens that the mountain summits are much warmer than the valleys, which are filled with cold air chilled by radiation from the surrounding hills. The height to which this lake of cold air extends is to be the principal subject of investigation. The station is well equipped with a complete set of the best instruments.

IN addressing the Liverpool Chamber of Commerce on Monday last, Major Ronald Ross gave an encouraging account of the progress in sanitary matters which is taking place in West Africa. The governors of the coast were, he said, doing everything in their power for the great cause of sanitation, and their efforts were supported by the Colonial Office, but this sudden and delightful reform was due principally to the action of the Liverpool School of Tropical Medicine. He was still convinced that for practical purposes as a rule drainage was the proper way of dealing with malaria in large towns. In spite of letters in the papers, the fact that mosquitoes carried malaria was an absolute one. They did not propose to destroy every mosquito throughout the continent of Africa, but to reduce them in towns by getting rid of the innumerable breeding places. From six years' special study of mosquitoes he assured them that this measure would have the desired effect. Apart from malaria they proposed to do everything in their power to improve the health of the West Coast in every way. Already they had opened with the British Bank of West Africa a tropical sanitation fund, and they would begin a campaign in Nigeria when they were able to open an account for that work. In his opinion the West Coast of Africa was not so unhealthy as it had been painted by some, and his own experience proved that those who lived carefully there would most likely succeed in avoiding severe diseases. The country was opening up every day, and as it opened up so would disease tend to diminish, as it did in India and Burma before the advance of civilisation.

THE Nordenskjöld South Polar Expedition left Gothenburg on the 16th inst. on board the *Antarctic*.

DR. D. MORRIS, the Imperial Commissioner o. Agriculture for the West Indies, who has been in London for the past few weeks, has now returned to Barbados.

At the recently held annual meeting of the Royal College of Surgeons, Edinburgh, the following prizes were awarded:—The Victoria Jubilee Lister prize of the value of 100*l*., founded by the late Dr. R. H. Gunning "for the greatest benefit done to practical surgery by any Fellow or Licentiate of the College during the quadrennial period ending June 20, 1901," to F. Mitchell Caird, of Edinburgh; the Surgical Essay prize of 100 guineas, offered by the College for "an original unpublished essay on surgery, in any of its branches on anatomy, physiology, therapeutics, or pathology, in their relations to surgery," to J. Veitch Paterson, of Edinburgh, the title of whose essay was "The Lymph Flow through the Eyeball."

THE Lecture List Calendar of the London Institution for the coming session is now ready, and includes the following addresses:—"On the Senses and Intelligence of Animals," by Lord Avebury; "The Life Period of Mountains," by Prof. G. A. J. Cole; "Optical Properties of Diamonds and Rubies," by Prof. S. P. Thompson; "Nourishment and Protection of the Young of some Animals," by Prof. C. Stewart; "Photographic Study of Clouds," by Mr. A. W. Clayden; "Conveyance of Malaria by the Mosquito," by Dr. P. Manson; "Recent Work among the Mollusca," by Prof. G. B. Howes; "The Heart," by Dr. H. Power; "The Mammoth Cave of Kentucky," by Mr. F. Lambert; "The Development of the Human Brain as an Organ of Mind," by Dr. F. W. Mott; "Colour Vision," by Mr. G. J. Burch; "Protection by Shape and Colour in Amphibia and Reptiles," by Dr. H. F. Gadow; "Inert Gases of the Atmosphere," by Prof. W. Ramsay.

ACCORDING to the daily papers a new principle in wireless signalling has been discovered by Mr. A. Orling and Mr. T. Armstrong, who last Friday gave a demonstration of the system which they have worked out. So far as we know, no description of Messrs. Orling and Armstrong's method has as yet appeared in the technical Press, and the details given by the newspapers being somewhat scanty it is difficult to form any definite idea of the probable utility of the system. We gather that the inventors rely partly, if not entirely, on earth conduction, and that they have been successful in transmitting speech in this manner. By using relays buried in the earth the range of signalling has been increased up to two and a half miles overland, a distance which, it must be admitted, is insignificant compared with Mr. Marconi's results. The system is, however, said to offer great facilities for tuning and thus to avoid the interference of messages, an advantage which should be of great benefit to it. The inventors appear to have devoted most of their attention to working out a method of controlling torpedoes or submarine boats from the shore. It may be recollected that in 1899 an account of some experiments made by Messrs. Jamieson and Trotter with this object appeared in the technical papers. These inventors used Hertz waves acting on a coherer on board the torpedo; although at the time it was said that the apparatus worked without a hitch, we have not since heard of its development or practical adoption. Messrs. Orling and Armstrong are said to have successfully guided a torpedo at a distance of six miles from shore.

AN excerpt from the *Proceedings* of the Royal Geographical Society of Australasia (Queensland) contains an illustration of the recently instituted "Thomson Foundation Gold Medal" of the Society. The medal, which is the work of Wyon, is to be awarded annually, or at such times as the council may approve, to the author of the best original contribution to geographical literature, preferential consideration being given to the geography of Australasia, provided it be, in the opinion of the council, of sufficient merit. The subject of the competition for the award of 1902 is "The Pastoral Industry of Australia, Past, Present and Probable Future," and essays must reach the Society not later than June 15 next.

AT the meeting of the Institution of Mining and Metallurgy held on Thursday last, an interesting paper was read by Mr. C. J. Alford on "Gold Mining in Egypt," in the course o. which he said that the exposure of the crystalline rocks in which the ancient gold mines of Egypt were worked, and in which search for deposits of metalliferous minerals might be undertaken with prospects of success, commenced about Jebel Zeit, at the south end of the Gulf of Suez, and extended in varying width along the coast line of the Red Sea, with few and slight interruptions for 700 miles, until it joined the mountains of Abyssinia. At Um Rus the mountain chain of crystalline rocks was about 60 miles in width from east to west, whilst 100 miles south it decreases to about 30 miles; then, in latitude 22° N., the boundary line between Egypt and the Sudan, it extended from the coast westward for fully 200 miles, and, with occasional covers of sand, all the way to the Nile. During the last twelve months the work of exploring the country and the ancient mines had been pushed on energetically. At Um Rus the exploration of one of the ancient gold mines was commenced last December, and so far the results had been decidedly encouraging. Speaking at the meeting at which Mr. Alford's paper was read, Lord Harris stated his willingness to undertake the responsibility that a gold medal, or whatever material object the council of the Institution might suggest, should be presented as a prize for the purpose they might think most useful.

According to the *Electrician*, difficulty has for some time past been experienced in maintaining communication with the observatory on the Zugspitze mountain, 3000 metres high, on the Austrian frontier of Bavaria, throughout the year. Last September the Bavarian Postal Telegraph Administration put the matter into the hands of the Allgemeine Elektricitäts Gesellschaft, who have now solved the difficulty by establishing a wireless telegraph installation between the observatory and the post-office of Eibsee on the Slaby-Arco system. The difference in altitude between the summit of the mountain and the Eibsee post office is 2000 metres. In designing the apparatus such a wave-length was chosen, so that deflection from the surfaces of rocks, &c., on the mountain should assist rather than impede the transmission of the signals. Another difficulty which has been overcome is that of the power supplied to the apparatus. The transport of heavy batteries, &c., to the top of the mountain would have been extremely difficult, and therefore the company has designed the apparatus so that it should require a minimum of power, and the dry cells which are employed with it have proved sufficient. Instead of the wire which has been used in many recent Slaby-Arco experiments, ordinary steel rope has been employed, and this has been fixed in a slanting direction to the surface of the rocks without the assistance of either a mast or insulators. It is stated that the system has so far given entire satisfaction to the Post Office authorities.

At the Trinidad Agricultural Exhibition specimens of sponges which had been collected on the beach of Tobago were on show. The sponges were not large, but were soft in texture, minutely porous, and the presence of large silicious spicules, so common in inferior kinds, was not apparent. They resembled very much what are sold as face sponges. In the specimens exhibited it was seen that the structure was tender and easily pulled to pieces, showing that they would not last long in use. It was explained, however, that the specimens were taken from the beach, and there was nothing to show how long they had been exposed to the rolling of the breakers, the heat of the sun, and the erosion of sand and pebbles of the beach, which would naturally tend to rot the texture of a sponge. Such, however, is the quality that it is thought, says the *Bulletin of Miscellaneous Information* (Trinidad), a trial might usefully be made by a skilled diver on the reefs where they are produced, to ascertain whether the quality would be of fair market value, if harvested direct from their habitat. Such an experiment would cost but little, and, if successful, would confer a blessing on the little Island of Tobago, so long hampered by financial difficulties. In the Bahamas the export for 1898 was valued at 97,512*l*. If the reefs of Tobago should prove as fertile of marketable sponges as those of the Bahamas, it would mean the establishment of a new and permanent industry of the highest value.

The Essex County Council is to be congratulated on the good work done in the technical laboratory at Chelmsford by Messrs. Dymond and Hughes. The "Notes on Agricultural Analyses" just issued contain a careful account of different descriptions of soil occurring in Essex, their geological and physical characteristics, and their chemical composition. This is just the kind of work which county councils may carry out with great advantage.

The annual report of the Connecticut Agricultural Experiment Station, just issued, furnishes a good example of the kind of work done at an American station. One half the volume consists of reports of the analyses of fertilisers, foods and other agricultural commodities; the other half deals with investigations, and discusses agricultural questions. One of the most interesting articles is on the kinds of trees most suitable for street avenues, and the diseases and accidents to which they are specially liable. Dr. T. B. Osborne continues his laborious researches upon the chemistry of vegetable proteids. A valuable bibliography of American work on plant diseases is supplied by Dr. Sturgis.

We have received a copy of Sir Charles Todd's Report upon the Rainfall in South Australia and the Northern Territory during 1898. Monthly and yearly values are given for a large number of stations and show that, generally speaking, the small annual average over the northern districts is mostly made up of summer rains, while in the southern districts the winter rains are largely in excess. As wheat growing chiefly depends upon the latter conditions, the monthly tables are very valuable for agricultural purposes. The annual distribution is clearly shown in two maps which accompany the report.

Mr. W. W. Wagstaffe, B.A., has printed an interesting little pamphlet on the climate and weather of Sevenoaks, based on observations for ten years (1890-99). The absolute maximum temperature was 89° in August 1893, and the lowest 5° in February of the severe winter 1894–5. The average annual rainfall is 29·75 inches, of which only about one-third fell during the daytime. The summer temperature is nearly 3° lower than London.

The first volume of the *Journal of Hygiene* has just been completed by the issue of part iv., which maintains the high standard of its predecessors. In it Rogers discusses the seasonal prevalence of *Anopheles* and malarial fever in Bengal, and his observations support the view that the disease known as Kala-azar of Assam, the ætiology of which has been doubtful, is an epidemic malarial fever and is transmitted by *Anopheles*. Nuttall and Shipley conclude their studies on the structure and biology of *Anopheles*, their paper being illustrated by some excellent plates. Cobbett surveys the epidemiology and bacteriology of a recent outbreak of diphtheria at Cambridge, and Fulton that of the Elkton (Maryland) milk epidemic of typhoid fever. The use of "neutral red" as a test for the colon bacillus and of its presence in waters is the subject of the remaining two papers by Makgill and by Savage. These two investigators, working independently and separately, arrive at practically the same conclusions. They find that this reagent is a very delicate indicator for the colon bacillus and that a negative neutral-red reaction obtained with a sample of a water is high presumptive evidence of the absence of this organism.

The current number of the *Berichte* of the German Chemical Society is remarkable for the number of original communications it contains, there being no less than 106, occupying 753 pages. Among these is a paper by Dr. Otto Ruff, on the existence of ammonium. It has been regarded as highly probable by many experimenters that on treating ammonium chloride solution with sodium amalgam or on electrolysing a solution of ammonium chloride with mercury as kathode, a real amalgam of ammonium with mercury is the true primary product. The problem is here attacked from a new and ingenious point of view, although with negative results. It is known that the alkali metals dissolve in liquid ammonia with the production of compounds possessing a fine blue colour. Thus a solution of potassium iodide in liquid ammonia submitted to electrolysis at a temperature of −70° C.

readily gives this blue compound at the negative pole. A solution of ammonium iodide in liquid ammonia was now substituted for the potassium salt, and then electrolysed at $-95°$ C., but no blue coloration was produced, hydrogen gas being steadily evolved from the commencement of the experiment. Thinking that perhaps an increase of pressure might have the desired effect the tube was sealed up, but although in one case the pressure rose to as much as 60 atmospheres before the tube burst, there was still not the slightest evidence of the existence of the radical ammonium in the free state.

THE same number of the *Berichte* contains an interesting paper, by H. Biltz, on the dissociation of the sulphur molecule. In recent years it has been shown by numerous researches that the maximum density of sulphur vapour corresponds to a molecule S_8 and not S_6 as usually represented in the text-books. But although this point is now well established, there was still a doubt as to the exact manner in which the molecule dissociated, the results of the first measurements of Biltz suggesting that the dissociation actually took place in two stages, the molecules S_8 first breaking up into S_6 and S_2, and these S_6 molecules finally splitting up into $3S_2$ molecules. In order to set this point at rest further measurements were carried out, the results of which are given in the present paper. The problem can be attacked in two ways; the densities can be determined at constant pressure, or at constant temperature with varying pressures. The latter method, giving isotherms, was selected as being capable of the greater accuracy, experiments being carried out at a temperature of 444° C. and at pressures between 14 and 540 mm. of mercury. The author concludes that only two kinds of sulphur molecules exist, S_8 and S_2, the former being the only ones present in sulphur solutions, the latter in sulphur gas at temperatures above 850° C.

A REPORT has been drawn up for the Franklin Institute on recent advances in the physics of water, by Dr. George Flowers Strading, and is published in the *Journal* of the Institute for October (pp. 257–269). It deals with the theory which assigns to water a complex molecular constitution, the maximum density and its dependence on the pressure, the relations between the pressure, volume and temperature, and the viscosity. In connection with the molecular constitution of water, the author discusses at some length Röntgen's theory, which regards water as consisting of two kinds of molecules called "ice molecules" and "molecules of the second kind." A subject somewhat allied to the above, namely the freezing points of solutions, was recently dealt with in the *Physical Review* by Messrs. E. H. Loomis and W. F. Magie.

THE *Mathematical Gazette* contains a brief account of the recent "Teaching of Mathematics" discussion by Mr. R. F. Muirhead, and a paper on the slide-rule by Prof. F. R. Barrell. We should like to see more matter of this kind in the pages of the *Gazette*, which, it may be remembered, is the organ of an association which till recently called itself the Association for the Improvement of Geometrical Teaching. The present is an opportune time for the Association to resume the functions expressed by its old title, and the fact that many of the members are engaged in teaching mathematics on conventional lines would add to the value of any opinions expressed in the *Gazette*.

IN a note contributed to the Lombardy *Rendiconti*, xxxiv. 16, Signor Alberto Dina compares the hysteresis in iron under a rotating, an alternating, and a statical magnetic field. In the first the magnitude of the inducing force remains constant and its direction varies, in the second and third the direction remains constant while the magnitude varies. The third case is distinguished from the first and second by the property that the complete cycle takes place much more slowly. The present experiments differ from those previously made in that the same body has been used in measuring each of the three kinds of hysteresis. The table of results shows clearly the behaviour of these different forms of hysteresis for equal induction; while the "alternating hysteresis" is always greater than the "statical hysteresis," the "rotatory hysteresis" lies between both of them until $B = 10,000$ units approximately; it then becomes equal to the statical, and afterwards less, and both the percentage difference and the absolute difference increase as the induction increases. These experiments were performed with iron of low permeability, and it is suggested that similar experiments with soft iron might yield interesting results.

IN addition to papers dealing with meteorological and physical subjects, Nos. 1 and 2 of the *Bulletin* of the Moscow Society of Naturalists for 1901 contain an important article by J. J. Gerassimow on the influence of the nucleus on the growth of the cell, and also one by Prof. D. Sernoff on the morphological nature of the tail-like appendages occasionally met with in the human race. After describing, with illustrations, several examples of these appendages, the latter author comes to the conclusion that they are teratological and in no sense atavistic.

IN the *Biologisches Centralblatt* for October, Dr. G. von Linden commences an account of his investigations into the structure of wings of insects, especially the Lepidoptera during the pupal stage, in relation to their origin and their bearing on the phylogeny of the different groups. The subject has been taken up where it was left by Schäfer, van Bemmelen, Haase, Urech and Eimer, and the theory of the latter that the original type of coloration in Lepidoptera was in the form of longitudinal stripes, while a uniform coloration is the final development, is confirmed. The bearing of the investigation on classification is left for a later communication.

IN the *Victorian Naturalist* for September Mr. W. Macgillivray concludes his notice of North Queensland birds, while Mr. R. Hall gives a further instalment of his notes on undescribed nests and eggs of Australian birds.

WE have received a copy of a paper by Miss N. Evans on the habits of the common grey mosquito of Calcutta (*Culex fatigans*), published in the August issue of the *Proceedings* of the Asiatic Society of Bengal. It is shown that the adult female may live for about five weeks, during which it may feed five times, when it selects by preference the blood of the house-sparrow. The latter fact suggests the possibility of this insect being a carrier of a definite blood-infection.

THE additions to the Zoological Society's Gardens during the past week include a Black-headed Lemur (*Lemur brunneus*), a Yellow-cheeked Lemur (*Lemur xanthomystax*) from Madagascar, presented by Mr. S. Neven Du Mont; two Arctic Wolves (*Canis occidentalis*) from New Mexico, presented by Mr. William Ruston; three Shaw's Gerbilles (*Gerbillus shawi*), a Dwarf Jerboa (*Dipodillus campestris*) from North Africa, presented by Mr. J. S. Whitaker; a Campbell's Monkey (*Cercopithecus campbelli*) from West Africa, two White-fronted Capuchins (*Cebus albifrons*) from South America, a Green-headed Tanager (*Calliste tricolor*) from South-east Brazil, two Dinca Finches (*Dinca grisea*) from Chili, a South Albemarle Tortoise (*Testudo vicina*) from the Galapagos Islands, a Rough Terrapin (*Nicoria punctularia*) from Northern South America, two Annulated Terrapins (*Nicoria annulata*) from Western South America, two Menobranchs (*Necturus maculatus*) from North America, two Dark Green Snakes (*Zamenis gemonensis*), a Four-lined Snake (*Coluber quatuorlineatus*), European; ten Snake Fishes (*Polypterus senegalus*) from the White Nile, East Africa, deposited; a Black-faced Spider Monkey (*Ateles ater*) from Eastern Peru, eight Golden Plovers (*Charadrius pluvialis*), European, purchased.

OUR ASTRONOMICAL COLUMN.

THE SPECTROSCOPIC BINARY CAPELLA.—The *Lick Observatory Bulletin* No. 6 contains the final values adopted for the orbit of the spectroscopic binary system of Capella. The reductions are from thirty-one observations of the radial velocity of the solar-type component, made with the Mills spectrograph between 1896 September 1 and 1900 September 27. On most of the plates the spectra of the two components are distinguishable, that of the principal star being of the solar type, whereas that of the secondary component is intermediate between the solar and Sirian types. The ranges in velocity are as follow:—

Principal star $+4{\cdot}2$ to $+55{\cdot}7$ kilometres per second.
Secondary ,, -3 ,, $+63$,, ,,

Therefore the ratio of the two masses will be as $1{\cdot}26 : 1$.

The solar-type component is estimated to be about half a magnitude brighter photographically than the blue component, while in the visual region of the spectrum the solar component is probably a whole magnitude the brighter of the two.

In consequence of observations with the 36-inch refractor under good conditions failing to show the duplicity of star, it is probable that the distance between the components is not greater than $0''{\cdot}06$.

The following are the final adopted elements, with their several probable errors:—

$\omega = 117^\circ{\cdot}3 \pm 18^\circ{\cdot}3$.
$\mu = 0{\cdot}060403 \pm 0{\cdot}000014$ radians.
$= 3^\circ{\cdot}46082 \pm 0^\circ{\cdot}00081$.
$T = -17{\cdot}4 \pm 5{\cdot}3$ days, the actual date being 1899 September 1·5.
$e = 0{\cdot}0164 \pm 0{\cdot}0055$.
$K = 25{\cdot}76 \pm 0{\cdot}12$.
$U = 104{\cdot}022$ days $\pm 0{\cdot}024$ days.
$a \sin i = 36{,}847{,}900$ kilometres.
$V = +30{\cdot}17 \pm 0{\cdot}104$ kilometres per second.

NEW SOUTHERN ALGOL-VARIABLE.—Mr. A. W. Roberts announces that observations made at Lovedale confirm the variability of the star,

R.A. = 10h. 16m. 44s. } 1875.
Decl. = $-41^\circ\ 43'{\cdot}8$ }

The observations suggest the following elements:—

Period = 1d. 20h. 30m. 2s.
Epoch of Min. = 1900, Jan. 1d. 15h. 10m. (G.M.T.)
Limits = 10·0–10·9 magnitude.

The actual light changes are completed in 3h. 20m., and there appears to be no stationary period at minimum. The ascending and descending phases are equal, each occupying 1h. 40m. (*Astronomical Journal*, vol. xxii. No. 508.)

SPECTRUM OF NOVA PERSEI.—In the *Astronomische Nachrichten*, Bd. 156, No. 3741, Father Sidgreaves summarises as follows the results of his examination of recent photographs of the spectrum of the Nova Persei:—

All hydrogen lines are now relatively weak, excepting the doubtful line $H\epsilon$.

λ5007 much stronger than $H\beta$ or $H\gamma$. Great width.
4958 prominent broad band.
4718 grown from a weak to strong band.
4713 strong line on edge of 4718.
4688 rather weak broad band.
4640 gradually weakened like hydrogen.
4364 very prominent band, stronger than $H\gamma$, crossed by three bright lines.
3969 ?$H\epsilon$. As strong as all other hydrogen lines together.
3869 stronger than 3969.

All these, with the exception of 4718, which shades off on red side, are broad with sharp edges. The structure of bands 3969 and 3869 very remarkable, being crossed by four strong lines of the same relative intensities and at the same intervals. This is also shown in the line 4364.

MICROMETRIC OBSERVATIONS OF NEPTUNE AND ITS SATELLITE.—In the *Astronomical Journal*, vol. xxii. No. 508, Prof. E. E. Barnard gives a series of micrometer measures of the satellite of Neptune extending over the period 1889 August 12—1901 February 5, made with the 40-inch refractor of the Yerkes Observatory. Many observations had been recorded previously, but it has been pointed out by Prof. Hall that only continuous measures of this object are of value. For the majority of the observations a power of 700 diameters was employed.

On three occasions it was possible to obtain good measures of the diameter of the planet, the reduced value being

$$d = 2''{\cdot}436 \text{ (at mean distance} = 30{\cdot}0551).$$

A note is made of the fact that the planet, when seen under the best conditions, always appeared round and free from markings.

APPEARANCE OF THE PHOTOGRAPHIC IMAGE OF NOVA PERSEI.—MM. Flammarion and Antoniadi contribute a further article respecting the photographic image of Nova Persei to the October issue of the *Bulletin de la Société Astronomique*, which is specially interesting in that it is illustrated by drawings and reproductions from the photographs obtained, showing exactly the appearances presented. These have already been described; the suggested explanation by Dr. Max Wolf ascribing them to the objective not being corrected for some special radiation emitted by the Nova does not appear to have been definitely settled yet, but the great intensity of the ultra-violet lines in its spectrum, together with the fact of the existence of the newly observed line about λ 342, would seem to support this supposition.

RECENT PROGRESS IN WATERWAYS AND MARITIME WORKS.

THE fourteen papers presented to the section of Waterways and Maritime Works at the International Engineering Congress at Glasgow were for the most part descriptive of important recent works carried out in various parts of the world, as, for instance, the Dortmund and Ems Canal, the Assuan Reservoir Dam across the Nile, the improvement of the Lower Mississippi, the Chicago Drainage Canal, the breakwaters for sheltering the entrance to the River Nervion, the Zeebrugge Harbour Works, and recent improvements in the lighting and buoying of the Scottish and French coasts. Some papers, moreover, dealt with the gradual extension and recent progress of works commenced many years ago, as, for example, the improvement of the River Clyde and its estuary and the works of Glasgow Harbour, recent improvements in the navigable condition of the Sulina branch and outlet of the Danube, and the lighting of the Chinese coast.

Some of these works furnish, for the most part, a record of the steady development and extension of methods of execution, constituting in the end a very notable advance, of which, however, the stages have been numerous and gradual; whilst other works present distinctly novel features, exhibiting a very definite progress in engineering science, and therefore of somewhat special interest, as will be briefly indicated.

The lift at Henrichenburg, on the Dortmund and Ems Canal, for raising barges of 950 tons from one reach of the canal to another, 46 feet higher, in a single operation, illustrates the novel principle of supporting the trough, carrying the barge, on several floats immersed in wells; and the whole structure is so perfectly balanced that the introduction of a small quantity of water into the trough at the top causes it to descend, and the abstraction of some water from the trough when at the bottom makes it ascend, the actual transit being effected in two and a half minutes, though the whole operation of transferring a barge from one reach to the other occupies about twelve and a half minutes on the average. This system of simple flotation, in place of the older system of hydraulic lifts, consisting of two counterbalancing troughs, each supported centrally on a hydraulic piston which even for raising barges of from 300 to 400 tons has had to be given a diameter of 6½ feet, has enabled these canal lifts, with their important advantages over locks of saving largely both time and water, to be adopted for vessels of more than double the tonnage of those raised by the older canal lifts.

The large excavations required for the Chicago Drainage Canal led to the adoption of excavators and dredgers of unusual size, the bucket of some dipper dredgers having been given a capacity of six cubic yards; whilst the removal of large masses of earthwork to the sides of the canal trench gave rise to the introduction of novel types of plant. These consisted of cableways suspended from high travelling towers on each side of the canal, along which skips conveyed the earthwork from the excavations to the spoil banks on either side; conveyors forming a bridge stretching across the channel, with cantilever arms projecting over the spoil banks on each side, carrying a steel travelling belt which conveys the material to the depositing ground; cantilever conveyors running on rails along one bank of the trench, with one arm dipping down into the excavations and the other rising over the spoil bank, up which incline a trolley is drawn for disposing of the earthwork; inclined planes leading to a travelling bridge with an open roadway extending over the spoil bank, through which wagons drawn up the incline deposit their load; and, lastly, high-power revolving derricks and other machinery for the rapid and economical removal and deposit of the excavations.

The novelty of the reservoir dam in progress at Assuan across the Nile consists in the one hundred and eighty sluices by which it is pierced affording a waterway of 24,000 square feet, through which the whole flow of the Nile in flood-time will be discharged, amounting to a maximum of 475,000 cubic feet per second with a velocity of 20 feet per second. These openings will be closed for storing up water for summer irrigation, by counterbalanced sluice-gates working on free rollers, which can be readily raised or lowered against a considerable head of water.

The deepening of the navigable channel by about 3½ feet outside the Sulina mouth of the Danube since 1895 by dredging, giving an available depth of 24 feet, shows that it is possible under favourable conditions to cope with the deposits of a minor channel of a deltaic river by means of dredging, at any rate for a time; though it must be anticipated that eventually the accumulations of deposit in front of the mouth will necessitate an extension of the jetties, to enable an improved scour across the advancing delta to aid dredging in the maintenance of the depth of the outlet channel.

The injuries caused during two successive winters to the superstructure on the top of a rubble mound, forming the main breakwater in progress for sheltering the approach to the River Nervion leading to the port of Bilbao, exposed as this breakwater is to the full force of the waves rolling in from the Bay of Biscay during north-westerly gales, has led to the adoption of a novel method of depositing blocks of concrete of unusual size for the purpose of providing a secure foundation for the superstructure in this exposed site, where the breakwater extends into a depth of about 50 feet at low tide. The method comprises the construction of metal caissons to serve as a lining for the blocks, which are ballasted with concrete, floated out into position, and sunk in place by filling them with water, after which they are filled as rapidly as possible with large concrete blocks, and with concrete in mass in the interstices and on the top, so as to constitute a solid block, the largest blocks thus formed at the Bilbao Harbour Works having a weight of about 1500 tons. These blocks, laid in a row on the top of a rubble mound at a depth of about 16½ feet below the lowest low water, within the shelter of the original rubble mound with its capping of large concrete blocks, have proved a perfectly stable foundation for the superstructure which is being erected upon them. This system is being extended at Zeebrugge Harbour in the North Sea, at the entrance to the Bruges Ship Canal, where steel caissons have been constructed and lined with concrete, which are to be floated into position in calm weather one by one for the foundations of sea and harbour walls along each side of a quay, and an outer solid breakwater; and these blocks, when completed, will rest on the sea bottom, and weighing from 2500 tons up to 4400 tons, will emerge about 2½ feet out of water at low water of spring tides, so that a solid superstructure can be readily built upon them.

Remarkable progress has been achieved in recent years in the extension of appliances for the more efficient lighting of minor shoals, outlying reefs, and navigable channels. The ease of rotation obtained by floating the illuminating apparatus on an annular mercury bath, has enabled the system of group flashes, giving a distinctive character to each light, to be extended to beacons exhibiting a continuously burning light for three or four months, by rotating the light apparatus by an electric battery placed in a chamber in the beacon. The increased speed of rotation, moreover, rendered possible by the floating on a mercury bath, has enabled the number of panels of lenses to be reduced and their size increased, and consequently a brighter flash to be exhibited. Various improvements also have been effected in the lights themselves. Thus carbonised wicks have been devised which enable a light to continue burning without being attended to for a considerable period, with only a moderate deterioration in intensity; incandescent lamps have been adopted, fed by oil gas or petroleum vapour, which provide an excellent light; and acetylene is being experimented upon by the French Lighthouse Service, and the danger of explosion having been overcome by using very small tubes for supplying the burner, it appears likely to furnish a very bright, serviceable light. Special attention has been lately devoted to reducing the divergence of the light exhibited by lightships from the vertical, as with a considerable rolling of the vessel in a storm the light is liable to be obscured for a time. As it has been ascertained by observation that the waves in severe storms have a fairly definite period of oscillation in any particular locality, the special period of oscillation of the waves where a lightship is to be placed is ascertained; and the vessel is so designed, and its weights adjusted, that its period of roll may differ materially from the oscillation of the waves at its station; and the roll of the lightship is further checked by giving it a large draught and deep bilge keels. Moreover, the light and its accessories are supported on a sort of compound pendulum, with weights so adjusted at the bottom and above the light that the oscillation of the pendulum differs from the roll of the vessel, and the stability and consequent visibility of the light is thereby increased.

Altogether the papers furnish interesting indications of some of the advances being achieved in the execution of waterways, maritime works, and the lighting of shoals and channels; and the prospect of important extensions of waterways is manifested by the Dortmund and Ems Canal, forming merely the first instalment of a waterway intended to connect most of the rivers of Prussia, and the proposal of a Russian engineer for constructing a deep waterway to connect the White Sea and the Baltic, capable of being traversed by large seagoing vessels.

ITALIAN GEOLOGY.[1]

AN elaborate memoir, containing results of a study of the rocks and geology of the basin of the Sesia with the exception of its lower portion, the Strona valley and the western portion of the Orta lake, has lately been issued. The authors remark that, having made traverses of this region in several directions, noting many stratigraphical details, they were obliged to recognise the impossibility of the task of determining the "absolute chronological value" of the different formations. Neither does their microscopic examination of the rocks help them more to unravel the stratigraphical problems. This is a result which is not infrequent where petrographical methods are treated as paramount. Petrography, as I have frequently laid stress upon, is but *an aid* to geology, a valuable one, I admit, but inferior to good and accurate field-work, lithology, and a wide general knowledge of the surrounding region, and especially of the habits in other regions of the same class of rocks.

The authors have, as they but too justly point out, to contend with the absence of any known fossiliferous horizon, or in fact any stratigraphical standard formation as a datum to work from. In addition a large mass of volcanics traverse the Valsesia between the two principal crystalline formations and produce uncertainty in the limits of each, further disturbing the already complex stratigraphical arrangement and masking the relations of one to the other. At the commencement of the paper is a bibliographical list of fifty-three memoirs dealing with the locality in question.

It was found convenient for the petrographical studies to divide the rocks of the higher basin of the Sesia into five groups:—

(1) Gneiss of Strona (with an appendix on the granites).
(2) Massive augitic and hornblendic rocks.
(3) Gneiss of Sesia (including the schists of Rimella and Fobello).
(4) Greenstones (pietre verde) properly so called.
(5) Gneiss of Monte Rosa.

The authors deserve much credit for not venturing beyond the old nomenclature of Gerlach and Parona, the earlier students of this region.

Under the first group are included mica-schists with silli-

1 "Ricerche Petrografiche e Geologiche sulla Valsesia," by E. Artini and G. Melzi (*Mem. del R. Istituto Lombardo di Sc. e Lett.*, vol. xvii. pp. 219–392; pl. xxii.).

manite, gneisses, biotitic granular, with two micas, scaly with microcline, fine grained biotitic, nodular amphibolic, dioritic, augito-hornblendic and fine-grained tormaliniferous; augitic granulites, amphibolites, olivine and serpentiniferous rock and calciphyres (*i.e.* crystalline calcitic rocks containing more or less various silicates). In the appendix is included an examination of the granitites of Roccapietra, Quarna, and some vein granites.

The second group comprises diorites—micaceous, augitic and hornblendic; norites—simple and with hornblende; gabbros—simple and with garnet and with olivine; peridotites, pyroxenites and hornblendites are represented by lherzolites, harzburghites and websterites. The banded gabbros and stronalites are represented by banded augitic gabbros, banded hornblendic gabbros, stronalites. Basic dyke rocks, as spessartites, amphibolites and dioritic schists, are each given their share of microscopic researches. Some interesting observations are offered concerning the occurrence of schistose structure in these rocks.

Under group three are included light-coloured schistose gneisses, mica-schists and prasinitic rocks. A notable fact in this formation is the presence of thick bands and big masses of truly massive granitoid rocks intercalated between the more schistose kinds. These are of different types in which the characteristic element may be microcline, quartz, or of the type

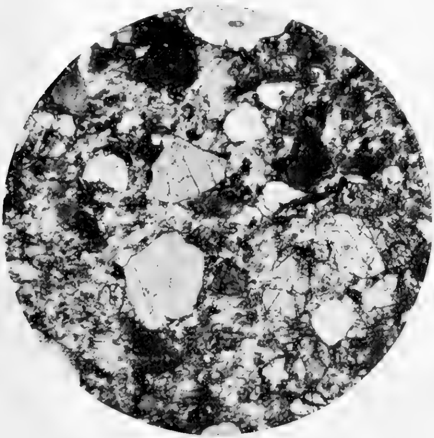


Fig. 1.—Calcifiro a Wernerite, con struttura clasticoporfirica.

of an augite-horneblende diorite. Though not attaining any notable development, still the nodular or *eyed* gneisses are interstratified with the other rocks of this formation, especially at Valle de Carcoforo and other localities.

Another member of this group which owes its structure to dynamic metamorphism is the finely-banded gneisses in the Val Grande. The structure of the limestones, calciphyres and schists of Rimella and Forbello are each carefully described.

The fourth group, included under the name of greenstones (pietre verde), though of less importance from the point of view of mass, present undoubtedly the most varied characters, such as prasinites, amphibolites, amphibolic schists, eclogites, serpentine, and oliviniferous rocks, calc-schists and saccharoidal limestones, garnetiferous mica-schists, and light-coloured gneisses and quartzite schists.

The final or fifth group, or gneisses of Monte Rosa, are remarkable for their uniformity of composition. The variations seem to consist chiefly of a porphyroidal, schistose, banded or tubular structure, passing by gradations to microgneisses and mica-schists.

The petrographical description of this large number of divers rocks and their varieties is very detailed, and appears to be done with much care. It is, of course, quite impossible to give even in outline a review of this in the space at our disposal. A clearer idea of the varied rock-structures is afforded by the large number of admirable photo-micrographs which the authors have executed themselves, and which are extremely well reproduced in the twenty plates devoted to this part of the subject.

The second section of the memoir is devoted to the geological characters of the rocks. Unfortunately, the authors are able to add little that is new, or add any facts of general interest. Observations of dip are recorded, as well as contact-phenomena between rocks of divers mineralogical and chemical composition. These physico-chemical effects seem to be most variable—highly developed at one spot, and hardly to be remarked at others; no attempt, however, is made to explain these variations.

The authors deny the absence of contact effects, as asserted by Schaefer and Salomon, and between the basic eruptive rocks and the gneiss of Strona, and give some striking examples. As to the basic eruptive rocks, the authors show they are posterior to the Strona gneiss, and discuss their relative age to the Sesia gneiss. The other groups are treated rather from the point of view of their petrographical characters than from their geological aspect.

Cleavage and foliation, the effects of dynamo-metamorphic processes, is well developed in one part of the region, and quite absent in another; but few details of the types of foliation,

Fig. 2.—Prasinite Cloritica, struttura microocellare.

and other changes, are offered the reader. The difference o interpretation of the relative ages and relations of the Strona and Sesia gneisses, with Parona, is fully portrayed in a tabular form of Messrs. Artini and Melzi's views.

The greenstones of this region the authors collegate, and even consider to be identical, with the greenstones of the Western Alps, lately pronounced by the *Comitato Geologico* to be Triassic and Liassic; whilst the gneiss of Monte Rosa they consider as Palæozoic or even Archaic.

A good geological map in colours of the region under consideration is given, and another coloured plate is devoted to sections. This work represents a great deal of patient labour in a difficult region, and, altogether, the authors are to be congratulated on their work. A little more charity to their opponents might here and there be allowed. It might also suggest itself to their mind that Germany does not hold a monopoly of petrographical research; that in France, and even in poor little England—not to speak of America, Norway, and other countries—many problems that are concerned in this memoir have been tackled, the published results of which might afford them some additional information.

H. J. Johnston-Lavis.

THE FUMIGATION OF FRUIT TREES.

THE systematic way in which fruit crops are protected from insect pests and other natural dangers in California has often been mentioned in these columns. Among the enemies of citrus plants are scale insects, or bark lice, and mites, to the consideration of which an article, by Mr. C. L. Marlatt, is given in the U.S. Year Book of Agriculture for 1900. The natural predaceous enemies of scale insects are various species of ladybirds, such as the Australian ladybird, which was introduced into California to control the fluted and black scales. The black

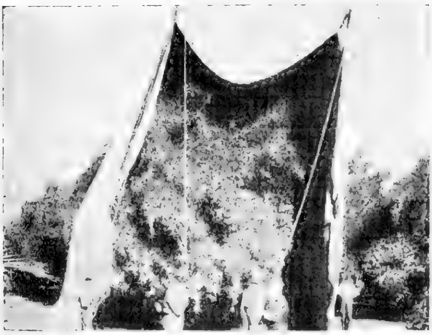

FIG. 1.—Tent carried over tree by the falling of pulleys.

scale has been completely controlled on certain ranches in the United States by its ladybird enemy, and this control has been brought about by the entire cessation of all insecticide operations. But until this condition of things exists on all the ranches, or at least until the natural enemies of scale insects have been fully studied, it is necessary to depend upon spraying and fumigation to keep down the insect pests. The most effective means of doing this is by subjecting infected plants to the fumes of hydrocyanic acid gas. The treatment consists in enclosing a tree at night with a tent as shown in the accompanying illustrations, and filling the tent with the poisonous fumes generated by treating refined potassium cyanide (98 per cent. strength) with commercial sulphuric acid (66 per cent.) and water. The treatment is particularly successful in getting rid

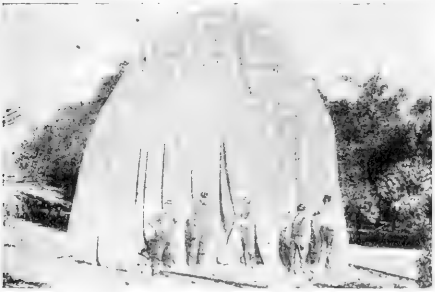

FIG. 2.—Tent in position for fumigation.

of the black scale (*Lecanium oleae*, Bernard) and California red scale (*Aspidiotus aurantii*, Maskell). The tents under which the trees are fumigated are drawn over the trees by means of pulleys, and some of them have diameters of more than seventy feet. To the fruit-grower who leaves things to chance, the work involved in the manipulation of such a protective process may appear excessive, but the cost must be regarded as insurance against loss due to defective crops, and the results obtained in California show that the expenditure of money and energy is fully justified.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MRS. ANNA HOUGH has offered 40,000 dollars to the University of Southern California at Los Angeles on condition that the balance of 100,000 dollars be raised. The University recently obtained from Mrs. Hough the sum of 25,000 dollars on like conditions.

DR. JAMES MUSGROVE, formerly lecturer in anatomy, was on Wednesday, the 16th inst., installed in the chair of anatomy endowed by the late Marquis of Bute, and instituted under the recent new ordinances in connection with the University of St. Andrews.

UNIVERSITY fellowships, each of the value of 100*l.*, have been awarded at the Victoria University, Manchester, to Drs. E. N. Cunliffe (Owens College) and G. W. Gelderd (University College), both of whom are undertaking research work during the coming year.

IN the expectation of further considerable grants by the local counties authorities, the council of the Birmingham University has, it is understood, authorised the Buildings Committee to prepare plans and specifications for necessary buildings, estimated to cost, without equipment and furniture, the sum of 200,000*l.*

THE following appointments are noted in *Science*:—Dr. J. B. Overton to be professor of biology, Dr. J. H. Hall, assistant professor of physics, each at Illinois College, Jacksonville, Ill., U.S.A., and Mr. F. B. Littell, of the U.S. Naval observatory, has been appointed to a professorship of mathematics in the U.S. Navy.

DR. J. BISHOP TINGLE, instructor of chemistry at the Lewis Institute, Chicago, formerly lecturer in chemistry at Gordon's College, Aberdeen, and at the Merchant Venturers' Technical College, Bristol, has been appointed professor and head of the newly organised department of chemistry at the Illinois College, Jacksonville, Ill., U.S.A.

THE new Municipal Technical College at Sunderland has started with the enrolment of 600 students. This number so largely exceeds the reckoning of the Technical Education Committee that the Borough Council, in order to provide for the necessary increase of the staff, will, it is expected, be compelled to have recourse to its rating powers.

THE dedication of the Severance Chemical Laboratory of Oberlin College took place on September 26, when an address was given by President Ira Remsen, of the Johns Hopkins University. In the course of the proceedings it was stated that Mr. Lewis Severance, the donor of the laboratory, had given the sum of 40,000 dollars as an endowment for the chair of chemistry.

AT a recent meeting of the governors of the Durham University College of Science, Newcastle, the principal of the College submitted his report, in which he stated that the fund for the completion of the College buildings amounted to 31,000*l.* The suggestion of their treasurer, Dr. Hodgkin, that a suitable memorial to Lord Armstrong would be to erect a statue upon some prominent site, and to dedicate the College to his memory, had received the hearty support of Mr. Watson-Armstrong, and was cordially adopted by the council. They resolved to ask the University to consent to a change of name, and to invite subscriptions to an Armstrong memorial fund. A public meeting was held, resolutions were adopted approving of the scheme, and upwards of 20,000*l.* was promised towards it.

SPEAKING at a meeting held on Wednesday, the 16th inst., to inaugurate the third winter session of the London School of Tropical Medicine, Dr. Manson said that the school wished to fulfil two functions, viz., the education of the practitioner who proposed to devote his life to practice in the tropics, and the attempt to advance medical science as regarded tropical disease. How far they had been able to fulfil those undertakings it was for those present to say. As regarded the educational part of their work he could claim that they had had a distinct success although they began with a certain amount of trepidation and anxiety. They had succeeded in overcoming financial difficulties and professional opposition, the first mainly through the assistance and countenance of Mr. Chamberlain and also with the assistance of the managers of the Dreadnought Hospital. From the first their student attendance was a fair one; but session after session the numbers of students asking for admission had increased, and now the applications were much more numerous than the accommodation they had to offer would allow them to admit. The mere physical space at their disposal was not sufficient to accommodate those who came to study there, and their appeal that day had for its object the removal of that obstacle to their success. The accommodation must be doubled if the school work was to go on. They wanted their laboratories very much enlarged; they wanted a lecture room, a room for a museum, and a good library. All these things were very necessary if the school was to go on and prosper. The work which the students of the school were doing warranted him in appealing for funds on its behalf. As instances of such work Dr. Manson referred to the investigation conducted by Dr. George Low in the West Indies respecting elephantiasis, the work of Dr. Durham and Dr. Myers in Brazil last year, and the new expedition of Dr. Durham to Christmas Island. The English Government, said the speaker, was very niggardly in regard to such matters compared with the German Government. Prof. Koch had forwarded to him, at his request, the following particulars of the subsidies granted to investigators working in connection with medical expeditions sent out under the auspices of the German Government:—"(1) Prof. Frosch in Brioni (Istria), (2) Staff-doctor Bludau in Lussinpiccolo (Istria), (3) Staff-doctor Vagedes in German South-West Africa, (4) Staff-doctor Dempwolff in New Guinea, (5) Staff-doctor Ollwig in German East Africa, (6) Dr. Krulle in the Marshall Islands. Further expeditions to Togo and Kameruns are being planned. The expeditions 1 to 5 have for their collective object, in the first place, the investigation of malaria, and form regular continuations of any malaria expeditions made to Italy, Dutch India, and New Guinea. Expedition No. 6 has for its object the investigation of syphilis and its different forms in the South Sea Island groups. The European expeditions 1 and 2 receive 20 marks (1*l.*) daily allowance, besides compensation for the various travelling expenses, outlay for the laboratory, &c. The "outside Europe" (foreign) expeditions receive 40 marks (2*l.*) daily, besides compensation for travelling expenses and outlay for scientific objects (books, instruments, complete laboratory arrangements, their upkeep, &c.), with a further 1000 marks (50*l.*) for personal equipment." The treatment thus accorded to German scientific expeditions was very much more generous than anything done for similar expeditions in this country, and he trusted that the school would receive generous accessions to its funds.

IN distributing the prizes at the Royal Technical Institute, Salford, on Friday last, Sir Henry Roscoe said it had often puzzled him to account for the singular apathy with regard to education which in times past, and to some extent even now, had characterised the average Englishman. Surely one would think that he of all men, dependent as he was for his very existence on his successful solution of problems relating to industry and commerce, would have felt it not merely an advantage, but an absolute necessity, that his knowledge and training should be as perfect and widespread as possible, just because the arts and trades which he practised had their foundation in artistic or scientific principles, and could only flourish satisfactorily under the guidance of those principles—that was, under educated effort. Whilst other countries—notably Scotland, Germany, the United States, Switzerland and France—long ago established their national system of schools, England up to 1870 was without one. Whilst Italy, Scotland, Germany and France in earliest times founded Universities which had remained as Universities of and for the people, the older Universities of Oxford and Cambridge had gradually become mainly high schools for privileged persons, and ceased to do for England what the Scottish Universities did for Scotland—that was, to be the Universities for all classes of the population, rich and poor alike. It must be the aim of the reorganised University of London to do for London's six or seven millions what the Scottish Universities had done for four millions of Scotsmen, and to become a real University for the people. England, however, was awakening. A new era in the history of English education began, first, in the foundation of the local University colleges, and, secondly, in 1890, in the passing of the Local Taxation (Customs and Excise) Act. The fact of the allocation of a sum of upwards of 750,000*l.* to technical and secondary education was an event unparalleled in the financial history of this country, and was in itself a proof of this awakening. That this act of the Government was appreciated was shown by the fact that the local authorities generally at once availed themselves of the opportunities thus presented. No less than upwards of 3,000,000*l.* had been expended by municipal and local authorities in providing technical schools throughout the land. Moreover, this progress had been unchecked by reverses or by waning interest; on the contrary, it had been continuous, universal and rapid. Still, much remained to be done. "Organise your secondary education" had been the cry from Matthew Arnold's day to our own. Yet nothing had been done in this direction by Parliament, with whom the duty lay. It was true that beginnings had been made; local authorities in some instances—and here he must name those of Manchester—had taken the matter into their own hands and had realised how necessary it was to consolidate and coordinate the education of various kinds existing in their midst, and actually had done so in advance of national action. The country had, he thought, made up its mind and would back any sensible plan for putting this part of our educational house in order. Let them unite in urging immediate action. Let them be satisfied with one thing at a time. If they saw that to put forward and to carry a measure which would bring about that which all desired—namely, that the various forms of educational effort should be organised as one compact whole—was at the present moment beyond the range of practical politics, let them not fail to secure the organisation of a part. This seemed to him to be common sense.

ON Tuesday last Mr. R. B. Haldane, K.C., M.P., delivered an address at University College, Liverpool, on "The Function of a University in a Commercial City," in the course of which he compared the position of education in this country with that in others, notably in Germany. Throughout the industrial world of Germany they found science applied to practical undertakings by men who had learned, if not in the Universities and high technical schools, at least under teachers produced by those institutions. This was true of a multitude of trades. In electrical engineering, in the manufacture of chemicals, in the production of glass and of iron and steel, and of many other articles for which Britain used to be the industrial centre, we were rapidly being left behind. A striking case was that of the aniline colours discovered and first produced in England and manufactured out of English coal tar. The industry had almost wholly shifted to Germany, although the dyers in this country were the largest consumers. The reason for this was that in Germany the manufacture had been fostered by research in the University laboratories and by careful teaching in the technical schools, with the result that great producing institutions, such as the Badische Anilin Fabrik, had an endless supply of directors and workmen trained in a fashion which we had not the means to imitate. But the school was in Germany by no means the only point at which the professor came to the aid of industry. Too little was known in this country of the type of institution sometimes called the "Central-Stelle," which had no parallel among our business men. This establishment, which was maintained by subscription at a cost of about 12,000*l.* a year, was presided over by one of the most distinguished professors of chemistry in the University of that city, with a staff of highly-trained assistants. To it were referred as they arose the problems by which the subscribers in their individual work were confronted. By it was carried on a regular system of research in the field of production of explosives, the fruits of which were communicated to the subscribers. The great manufacturers were in constant communication with the establishment, in which they took the keenest interest. In this country, it was needless to say, there existed nothing of the kind. And yet we had to compete with the Germans, not only at home, but in such important markets for explosives as South Africa, where their use was the life of the huge mining industry. Proceeding, Mr. Haldane alluded to the German academic institutions and compared them with the University system of this country, and made a number of suggestions which, if carried out, would, in his opinion, tend towards a better system of education and be for the benefit of the country. The conclusion of the whole matter, said Mr. Haldane, seemed to be that we could establish in Great Britain and Ireland a system of teaching of a University type, with the double aim of the system of Germany, and that without injury to quality in culture.

SOCIETIES AND ACADEMIES.

MANCHESTER.

Literary and Philosophical Society, October 1.—Mr. Charles Bailey, president, in the chair.—Mr. W. E. Hoyle exhibited two ethnological specimens from Demerara, formerly in the possession of the Manchester Natural History Society, under the name of "fish-arrows." They are about 4 feet long, slender, and apparently made from the wall of some hollow reed, with nodes at regular intervals. At one end is a barbed point of wrought iron, the other end being stained a dark brown for about four inches. The use of these weapons is somewhat difficult to determine; they are too thin and flexible either to shoot from a bow or to throw with true aim. Instruments of a similar kind have, however, been used for catching fish by baiting the barbed end and sticking the other end into the bed of the stream among the reeds.—Mr. Cecil P. Hurst sent specimens of *Diotis candidissima*, Desf., a disappearing British plant, which he collected recently on the sandy bars separating two inland lakes from the sea on the south-eastern coast of county Wexford, Ireland. He described its habitat on the shores of Lady's Island Lake and Tacumsin Lake, and on the coast from Carnsore Point westward, and referred to its recorded occurrence in nine of the comital areas in the South of England, from all of which, including the Channel Islands, it has disappeared. It was found very sparingly on the south-western coast of Anglesey in the years 1894 and 1896.

PARIS.

Academy of Sciences, October 14.—M. Bouquet de la Grye in the chair.—New series of experiments relating to the action of hydrogen peroxide solution upon silver oxide, by M. Berthelot. A thermochemical comparison of the action of acids upon oxide of silver before and after the action of hydrogen peroxide. The results are regarded as proving conclusively that a peroxide of silver is formed in this reaction, and that the evolution of oxygen is due to the decomposition of this compound.—On the variation of races and species, by M. Armand Gautier. Experiments by Molliard, and by Charabot and Ebray, on the influence exerted by the attack of certain insects on the development of certain plants, and the researches of Daniel on grafting, are held by the author to prove that the Darwinian principles of the influence of medium, of adaptation and of natural selection are insufficient to explain the profound and rapid modifications which have here taken place.—Two new hæmogregarians of fishes, by MM. A. Laveran and F. Mesnil. A detailed description of two new parasites of the sole and blenny, to which the names *Haemogregarina bigemina* and *Haemogregarina Simondi* are given. The paper is illustrated with seventeen drawings of the parasites in various stages of development.—The influence of variations of temperature on the evolution of experimental tuberculosis, by MM. Lannelongue, Achard and Gaillard. Neither a moderate degree of cold nor slight variations of temperature have any marked influence upon the development of experimental tuberculosis in guinea-pigs. On the other hand, brusque variations of temperature, although compatible with the life of healthy guinea-pigs, have accelerated in a remarkable manner the course of the disease.—On waves which may persist in a viscous fluid, by M. P. Duhem.—The elliptic element of the comet 1900*c*, by M. Perrotin. Measurements of the position of this comet, which was discovered by Giacobini on February 11, have been made in the observatories of Nice, Lick, Besancon, Algiers, Heidelburg and Strasburg, and show that it belongs to the curious group of periodic comets supposed to have been captured by Jupiter. The return of this comet may be expected in about seven years.—On the periodic integrals of binomial differential equations, by M. A. Davidoglou.—On the points of inversion of solutions, by M. Albert Colson. It is known that the specific heat of a solution is not the mean of the specific heat of its constituents, and hence it follows that the heat of solution and the heat of combination are variable, and at a fixed temperature some heats of solution change their sign. For solutions of common salt this point of inversion is found to be at 52° C.—The action of urea upon pyruvic acid. Homoallantoic acid and pyruvil, by M. L. J. Simon. It is shown that in this reaction, which has been previously studied by Grimaux, there is an intermediate compound formed, homoallantoic acid, and that the formation of pyruvil is due to an internal condensation of this compound.—The nitro-derivative of pentaerythrite, by MM. Leo Vignon and F. Gerin. The pentaerythrite, $C(CH_2OH)_4$, was prepared by the interaction of aldehyde, formaldehyde and lime water, and was found to possess no reducing power towards Fehling's reagent. The nitric ester was prepared and found to be the tetra-derivative; it was devoid of reducing power, and hence it is probable that the nitric esters which do possess reducing power have a constitution which is different from that usually ascribed to them.—On the free phase of the evolutive cycle of the orthonectides, by MM. F. Caullery and F. Mesnil.—Marine poisons and the burrowing habit, by M. G. Bohn. It has been found that sea-water in which certain red algæ have been growing is very poisonous, but that it loses this poisonous property on filtering through sand. Burrowing animals have thus the double advantage of mechanical and chemical protection.—On the eruptive rocks of Tilai-Kamen (Ural), by MM. L. Duparc and F. Pearce.—On a green colouring matter extracted from the blood of animals poisoned by phenylhydrazine, by M. Louis Lewin. The green substance, for which the name of hemoverdine is proposed, is not apparently a phenylhydrazine derivative, but a product of metamorphosis of hæmoglobin.—The spectrum of this substance is absolutely different from that of hæmoglobin or of any of its known transformation products.—The microphyte of the Piedra, by M. P. S. de Magalhaes.—On the mechanism of the formation of fine pearls in *Mytilus edulis*, by M. Raphael Dubois.

PTERODACTYLES.

Dragons of the Air: an Account of Extinct Flying Reptiles. By H. G. Seeley. Pp. xiii + 239. Illustrated. (London: Methuen and Co., 1901.) Price 6*s*.

EVER since the study of fossil remains was taken up in earnest, pterodactyles, or, as the author elects often to call them, ornithosaurs, have attracted the deepest attention on the part of anatomists on account of the many puzzling problems connected with their organisation and affinities, while from their weird form, peculiar attributes, and the huge dimensions attained by some of their later representatives they have appealed more strongly to popular interest than is the case with many of their extinct contemporaries. Among all the diligent students of the organisation of these strange creatures (so far as it can be worked out from their bones alone) none has been more constant or more persistent than Prof. H. G. Seeley, who commenced his investigations when a student at Cambridge during the late 'sixties. At that time the so-called coprolite-works in the Cambridge Greensand were in full swing; and the rich, albeit much broken, material thus obtained afforded opportunities for studying the structural details of pterodactyle bones in a manner impossible when dealing with the embedded skeletons of the smaller forms from the lithographic limestone of the Continent. Of these opportunities—both as regards study and collecting—Prof. Seeley availed himself to the full; and from that time to this, as occasion presented itself, he has, we believe, continued faithful to his favourite study. During the latter years of Prof. Sedgwick's tenure of the Woodwardian Chair at Cambridge, Prof. Seeley delivered a series of lectures at various centres—including the Royal Institution—on pterodactyles; and the present volume purports to be a reissue of these lectures in an expanded form, with such revision as has been rendered advisable by the progress of investigation.

In this volume Prof. Seeley appeals, as he tells us in the preface, alike to the general public and to the man of science. To achieve success in this double *rôle* is by no means an easy matter; and it may be questioned whether he has not given too much elementary explanation to suit the latter class of readers and not enough for the needs of the former. This, however, is a matter which concerns an author and his publisher rather than a reviewer.

All who have been occupied in investigating the osteology of pterodactyles can scarcely fail to be struck with the marked similarity presented in many respects—especially in the skull and cervical vertebræ—to birds. And this avian resemblance seems to have impressed itself with peculiar force on the mind of the author, who has all along contended that these creatures are not entitled to be ranked as reptiles, but form an outstanding group by themselves, displaying very widespread affinities with other groups of animals. So widespread, indeed, does Prof. Seeley regard the relationships of pterodactyles that it is by no means an easy matter to understand what his opinions on this subject really are, especially as his sentences are not unfrequently so involved that it is difficult to grasp his meaning. Even, however, if they cannot agree with them (or in some cases even understand them), the views of such an experienced and earnest investigator on a subject he has made specially his own should command respectful attention on the part of those whose knowledge in this respect is less extensive than that of the author.

Perhaps the best way of endeavouring to convey an idea of the author's views on pterodactyle relationship—which is the leading feature of the book—will be to quote his own words.

Selecting a few passages in serial order, we find it stated on p. 58 that[1]—

"While these animals are incontestably nearer to birds than to any other animals in their plan of organisation, thus far no proof has been found that they are birds, or can be included in the same division of vertebrate life with feathered animals."

On p. 188 we are told that—

"It is not so much that they mark a transition from reptile to bird, as that they are a group which is parallel to birds, and more manifestly *holds an intermediate place than birds do between reptiles and mammals*."

Again, on p. 210 we find the following:—

"Therefore there is a closer fundamental resemblance between some carnivorous dinosaurs [*e.g. Coelurus*] *than might have been anticipated*."

On the following page it is stated that—

"The dinosaurs, like pterodactyles, must be regarded as *intermediate* in some respects *between reptiles and birds*."

Finally, on p. 223, we have the following:—

"It would therefore appear from the vital community of structures with birds, that pterodactyles and birds *are two parallel groups*, which may be regarded *as ancient divergent forks* of the same branch of animal life, which became distinguished from each other by acquiring the different condition of the skin, and the structures which were developed in consequence of the bony skeleton ministering in different ways; and with different habit of terrestrial progression, this extinct group of animals acquired some modifications of the skeleton which birds have not shown. There is nothing to suggest that pterodactyles are a branch from birds, but their relation to birds is much closer, so far as the skeleton goes, than is their relation with the flightless dinosaurs, with which birds and pterodactyles have many characters in common."

Other passages might be quoted, but the foregoing are sufficient to indicate the extreme complexity of pterodactyle relationship according to the author. Personally we must confess to a total incapacity to draw a mental picture of the relationships thus indicated; and we have also failed in the attempt to construct a diagram which will show how groups that are divergent are yet parallel.

We have also yet to learn that birds are in any respect intermediate between reptiles and mammals; while we totally fail to see how any animals can be, *even in some respects*, intermediate between reptiles and mammals on the one hand, and reptiles and birds on the other. That is to say, in the sense in which we understand the term "intermediate," as indicative of descent.

[1] The italics introduced into these quotations are the reviewer's.

Again, as suggestive of prejudice, we must take the strongest exception to the author's use of the expression "than might have been anticipated" in connection with the affinities between pterodactyles and dinosaurs. What right had anybody to form "anticipations"?

If the author really intends to imply that birds and pterodactyles are divergent and specialised branches from groups of reptiles which cannot yet be identified (at all events in the latter case) with any approach to certainty, we can agree with him. But this by no means implies any intimate relationship between the two branches in question, the structure of the limbs of which is alone amply sufficient, in our opinion, to demonstrate their totally different origin. In urging an affinity between birds and pterodactyles, Prof. Seeley, in addition to the (may we say superficial ?) resemblances between their skulls and brains, lays stress on the fact that both have pneumatic bones. This feature is taken as an indication that pterodactyles probably possessed warm blood, from which is drawn the further inference that they were also furnished with a four-chambered heart. Even if the first inference be well founded, the second by no means follows, the author himself quoting the fact that the blood of the tunny has a temperature of 90°. And even if pterodactyles were warm-blooded and furnished with an avian type of heart, we should be none the more inclined to admit their affinity with birds.

Apparently the author takes no account of similar modes of life leading to the development of superficially similar bodily structure in totally different groups of animals, and the consequent "convergent" resemblance between them. And if this be so, his premises are so widely different from those on which the investigations of others are based that it is little wonder irreconcilable diversity of view results.

An instance of this nature occurs on p. 219, where we find the statement that "a few characters of ornithosaurs are regarded as having been *acquired*, because they are not found in any other animals, or have been developed only in a portion of the group." In one sense all characters are acquired; but the use which the author makes of the term "acquired characters" does not correspond with its ordinary scientific acceptation. From this we may perhaps infer that in other instances the signification attached to terms is different from that usually in vogue—which would account for much.

It is not, however, solely in regard to the affinities of these reptiles, as we still take leave to call them, that the author differs so much from current views. He likewise attributes to pterodactyles a bodily form quite unlike that with which they are generally credited; and one, it may be said, which makes them the most grotesque and bizarre creatures that ever walked this earth. But could they walk at all, as thus restored? is a question which can scarcely fail to occur to those who look on these wonderful pictures. In most or all other restorations, as in the plate by Smit in Hutchinson's "Extinct Monsters," pterodactyles, when not flying, are shown crawling on rocks or cliffs, or sitting up on their hind legs on some prominence preparatory to taking flight. Prof. Seeley will, however, have nothing to say to such crouching attitudes, and represents the creatures standing on all fours, with the greatly elongated wing-finger bent back alongside the fore-arm and projecting above the hind-quarters, and the wing folded like an inverted Chinese sun-shade. Whether such slender hind-limbs as are shown in the restoration are capable of supporting the weight of the body in this position we will not pause to inquire. Our difficulty is in connection with the fore-limb, the raising of which would apparently cause the wings to strike against the ground at every step, even if they did not become entangled with the hind-legs. Moreover, the creature is represented as actually standing on the joint between the metacarpus and the wing-finger, and as this joint must certainly have been a highly delicate and complex structure, it appears impossible to conceive how it could have escaped injury in walking if carried in the position shown in the restoration. Possibly the author has an explanation of these difficulties, but if so it would have been more satisfactory had it been given to the public.

To revert, in conclusion, to the main argument of the book, we fully realise the amount of labour that Prof. Seeley has expended on a very difficult subject, and at the same time are prepared to admit the advantage which often accrues to the progress of science from the presentation of opinions widely different from those generally entertained. Nevertheless, we scarcely think that he will persuade those of his readers whose verdict is worth having to agree with him in regarding pterodactyles and birds as in any way near akin, or will convince them that the former creatures are no longer entitled to be classed as reptiles. Aberrant they are, no doubt, but not so much so as, in our opinion, to be excluded from the limits of a class comprehensive enough to embrace such diverse types as dinosaurs, turtles, ichthyosaurs and snakes. As to the alleged relationship between the "dragons of the air" and the egg-laying mammals, we are fain to confess that it requires a greater power of imagination to realise the nature of the affinity than it falls to our own lot to possess.

R. L.

ELEMENTARY DYNAMICS.

Theoretical Mechanics: an Elementary Treatise. By W. Woolsey Johnson, Professor of Mathematics, U.S. Naval Academy. Pp. xv+434. (New York: John Wiley and Sons. London: Chapman and Hall, Ltd., 1901.) Price 3 dollars net.

THE author states in his preface that "the study of mechanics is here supposed to follow an adequate course in the differential and integral calculus." Hence it is difficult to see how it can appeal to any class of students—at least in this country—especially as, in addition to both branches of the calculus, the conceptions of geometry of three dimensions are also introduced at the outset. The student who has already progressed thus far in mathematics does not require to be introduced to the parallelogram of forces and all the elements of the composition and resolution of coplanar forces and velocities. There is nothing distinctively novel in the work, which is, on the whole, a careful compilation from the works of the best writers on the subject, without any acknowledgment of the sources.

The first two chapters deal with forces acting on a particle, and make free use of the calculus and geometry of three dimensions. In chapter iii. the author settles down to the composition, resolution, and equilibrium of a general system of coplanar forces, and gives a very good exposition of the subject; but in this chapter, of nearly fifty pages, no use of either the calculus or three-dimensional geometry is made, except in three pages devoted to the common catenary. Now the understanding of this very important and extensive section of dynamics is well within the power of any student even if he is quite ignorant of these branches of pure mathematics, so that it seems a pity that he should be kept back in his dynamical studies until he has passed through "an adequate course in the differential and integral calculus."

Passing over chapters devoted to the determination of centres of gravity and the composition of forces which are not coplanar, we come to chapter vii., which treats of the principle of work. This chapter is somewhat meagre, consisting mainly of what is known as "book-work," and not containing sufficient illustration of the applications of the principle to concrete cases. Until the student comes to chapter viii. he will experience no difficulty in the author's treatment of the subject; but when he reaches this chapter, on "motion produced by constant force," he will find a good deal about the nature of "inertia regarded as a force" which will be very perplexing. His main difficulty will be to decide whether the author means the "force of inertia" to be one exerted *by* a body or *upon* it by some agent or medium. Thus, at the beginning of art. 288 it would appear to be a force exerted *by* the body:—

"The property of matter through which *it resists* any change of motion, in accordance with the First Law of Motion, is called Inertia."

But a few lines farther on we have the sentence:—

"Now, just as the resistance of a fixed body in contact with that upon which the force acts, and preventing its motion, is regarded as a force equal and opposite to the force which would otherwise produce motion, so the resistance to motion in the body when free is regarded as a force equal and opposite to the active force which produces the motion."

Let us suppose a particle M acted upon by forces whose resultant is P and kept from moving by the resistance, N, of a fixed surface B; then the force N is exactly equal and opposite to the force P. Again, imagine the body M acted upon by the same force P and unresisted by any fixed surface; M will have an acceleration a, and the statement is that there is acting on M a force resisting the acceleration a—this force being clearly produced by something which in our thoughts replaces the above fixed surface B—that this force is equal and opposite to "the active force which produces the motion." So far, what this "active force" is is not clear; but the next sentence defines it:—

"Thus the force of inertia acts upon a particle of mass m only when there is an acceleration a, and its value is ma, while its direction is opposite to that of the acceleration."

Now observe that if the particle had no acceleration, this force would be zero, while in the first part of the analogy (where also $a = 0$) the supposed analogous force, N (the resistance of the surface B) is not zero.

However, from this and from subsequent statements it is clear that, in the author's view, a force of inertia really acts on a particle m which has an acceleration a, and that this force is scalarly and vectorly equal to $-ma$; that is to say, it is D'Alembert's fictitious "reversed effective moving force." But this is not in accordance with the statement at the top of p. 288:—

"And the inertia which acts upwards is, at that point, simply the resistance of the body to being moved away from the tangent at O."

It is certainly strange that a force acting *on* a body should be the resistance of the body to being moved. The author, however, clearly defines his conception, which he calls that of "kinetic equilibrium," at the top of p. 244:—

"For example, suppose a man whose weight is W to be standing on the floor of an elevator which begins to descend with the known acceleration a. The forces acting on the man are his weight, $W = mg$, acting downward, his inertia, ma, acting upward because the acceleration is downward, and the resistance R of the floor of the elevator acting upward. Since the forces are all vertical, there is but one condition of equilibrium, namely, $W = R + ma$."

The objection which a student will raise to this is that if the man is really acted upon by the upward force ma, the man is really at rest and not in motion at all.

D'Alembert never attributed anything but a fictitious existence to his "reversed effective forces," and he was right and consistent all through. The real objection to his principle is that it teaches us to be dissatisfied with the actuality (viz. motion), and to seek refuge in a fiction (viz. rest). The teaching of Newton's second axiom is quite different: it accepts motion as a fact and deals with it.

The remainder of the book gives somewhat short and easily readable discussions of central orbits, motion (especially uniplanar) of rigid bodies, moments of inertia, and impulses.

OUR BOOK SHELF.

The Earliest Inhabitants of Abydos; a Craniological Study. By D. Randall-Maciver. Plates viii + tables 16. (Oxford: Clarendon Press, 1901.) Price 10*s*. 6*d*. net.

IN the present work Mr. Randall-Maciver presents to the public the craniological material which he obtained in Upper Egypt in the winter of 1899-1900, and the results which he has deduced from it. In a series of eight plates he gives us photographs of a large number of skulls which he obtained from two cemeteries at Abydos, which, he says, belonged to the earliest and the latest stages of the pre-dynastic period, and to these he adds some sixteen tables of minute craniological measurements. The first cemetery contained only pottery of the earliest forms, black-topped, polished red, and white ornamented red, and the second degraded wavy-handled vases and other pottery of well-defined classes. The remarks which Mr. Randall-Maciver makes in his short preface may be regarded as a continuation of those expressed in his "Libyan Notes," and we observe that he still holds the view that the theory of the Libyan origin of the pre-dynastic or proto-dynastic Egyptians is "based on wholly inadequate evidence." The pre-dynastic Egyptians were, he thinks, a mixed race, but as a whole that race was not Berber; on the other hand, he does not deny the existence of an original Berber substratum, though he believes that its existence requires to be proved. A question of the kind must be decided by "expert anthropologists," for "archæology has its own place, and should recognise its own limitations; it can prove connections of culture, but not identities of race." We can only hope that the archæologists who hold different views from those of Mr. Randall-Maciver will take these observations to heart and turn from the error of their ways. It is, we must confess, a little disconcerting to find such a strictly scientific authority as Mr. Randall-Maciver reduced to suggesting that "it is well worth considering whether the pre-dynastic race of Egypt is not in the main a blending in various proportions of Semite and Negro." It is much to be hoped that his promised work on the whole subject will clear up some of its difficulties, but it seems doubtful, judging by the work of Mr. Randall-Maciver and Prof. Sergi, whether the archæologist will obtain much useful help from the craniologist.

The New Basis of Geography. A Manual for the Preparation of the Teacher. By Jacques W. Redway. Pp. xvi+226. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1901.) Price 4*s*. 6*d*. net.

NOT that the basis is really "new," for the author, who is perhaps the most successful writer of geographical school-books in the English tongue, knows a great deal better. In his preface he says in effect that the novelty of his basis is only apparent to the ignorance of the average teachers, and the newer they find it the more shame to them. "This book," he explains, "is intended to set forth in an elementary manner the relations between human activities and geographic environment." It does so very well. The style is facile and free, permeated by an air of genial familiarity with the subject, and with the class of reader appealed to. There is a tendency to semi-epigrammatic sentences, shattered fragments of which will be recognisable in the breccia of the pupil-teacher's examination papers for a generation to come:—"War has its horrors, but it is less horrible than ignorance." "Accuracy is the one virtue that cannot possibly belong to a flat map." "It is not necessary to worry about the plane of the ecliptic."

The last proposition will probably be popular, if one may say so without disrespect to other "imaginary lines."

Mr. Redway has produced a thoroughly practical, well-informed and thoughtful book; one which can not only be read with pleasure by the teacher in the study, but practised with profit in the school. True, it does not accord with any of the "codes" in this country, but the principles it lays down will be found perfectly amenable to any pattern of red-tape harness. Stress is laid on the superiority of the method of teaching by letting the pupil discover his own facts—"The reading method might fit a young man to be a private secretary; the discovery method fits him to be the employer of private secretaries."

References to books are given as well as hints on method, and Mr. Redway is generous in commending the works of other writers. We feel sure that his strongly practical exposition of the nature and value of geographical principles will do more to promote sound geographical education than any amount of learned advocacy by theorists can ever accomplish.

Expertises et Arbitrages. By F. Rigaud. Pp. 177. (Paris: Gauthier-Villars. Masson and Co., 1901.)

IN this volume, which belongs to the Encyclopédie scientifique des Aide-Mémoire series, the author gives a *précis* of standard legal works on reports and arbitrations, and summarises the principles and laws which should be considered by arbitrators and experts more familiar with technical knowledge than law. From this practical point of view the book may prove of service.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Note on a Point of Chemical Nomenclature.

SENIER AND GOODWIN have, in a recent paper (*Journ.* Chem. Soc. vol. lxxix. p. 258), made use of the term "alphyl" as a generic name for the aromatic radicles. The continued use of this term with the meaning attached to it by the above authors is one which may lead to some confusion. It is undoubtedly of advantage to be able to distinguish by special names fatty from aromatic radicles. With this end in view Bamberger proposed some time ago (*Berichte*, xxvii. 2583) "*alphyl*" as a general term for aromatic radicles, such as phenyl, tolyl, &c. He derived this word from "alkyl-phenyl," and as it supplied a want it was speedily adopted by investigators and appeared in scientific papers and text-books. Vorländer in 1899 (*Jour. für praktische Chemie*, lix. 247) drew attention to the possibility of error centred in the new name. As he remarked, every student of chemistry on hearing the word "alphyl" for the first time would think, not of an aromatic compound, but of one belonging to the fatty or aliphatic division. He then pointed out that *alphyl* was, on the contrary, a thoroughly suitable name for a monovalent hydrocarbon radicle of the fatty series, and that an aromatic radicle might be designated by "*arryl*."

For monovalent fatty radicles we have the name "*alkyl*" suggested years ago by J. Wislicenus and derived from "alcohol." There is no reason for superseding that term, but its meaning might with advantage be enlarged. Vorländer's proposal was that *all* monovalent hydrocarbon radicles, whether fatty or aromatic, should be called "*alkyl*" groups, this term being in opposition to "*acyl*" used by Liebermann (*Berichte*, xxi. 3372) for acid-radicles. We may then subdivide the alkyl group into fatty and aromatic divisions, giving each a special name.

The following scheme sets forth the proposed nomenclature:—

I. *Alkyl.* All monovalent hydrocarbon radicles.
(*a*) *Alphyl.* Aliphatic radicles (CH_3, C_2H_5, &c.)
(*b*) *Arryl.* Aromatic radicles (C_6H_5, &c.)
(*c*) *Alpharryl.* Aromatic radicles possessed o. a fatty character (benzyl, &c.)

II. *Acyl.* Acid radicles in general ($CH_3.CO$, $C_6H_5CH_2CO$).

Bamberger, the proposer of the term "alphyl" for aromatic radicles, acknowledged the ambiguity and adopted Vorländer's proposal (*Lieb. Ann.* cccv. 289). One modification he suggested, and this was the change from "arryl" to "aryl." Since that time he has used in all his work the term "aryl" where he previously used "alphyl." This is a custom which now generally obtains in Germany, and "alphyl" in its original sense has almost altogether disappeared from papers and text-books. Should now the term "alphyl" be used in England for an aromatic radicle, it will creep again into such reference periodicals as the *Centralblatt* and there occur side by side with "alphyl" and "aryl" in their later meanings, as has already been the case, and this will lead to manifest lack of clearness and confusion. Some English chemists use "aryl" for an aromatic radicle (*cf.* Sudborough, on acetylation of arylamines, *Proc.* Chem. Soc. xvii. p. 45). It would therefore be of great advantage to agree on a uniform use of these different terms.

A. T. DE M.

Folklore about Stonehenge.

I REMEMBER, when I was a child, between seventy and eighty years ago, being told that the stones could be successfully counted only by laying a loaf of bread beside each. To mark each stone by something to prevent one being missed or counted twice over seems natural; but why a loaf of bread? Is this an idea surviving from the "*cultus lapidum*" referred to in your review of "Carnac and Stonehenge" in NATURE of September 12? I think it probable that I had this from a nursery-maid who came from Mere in Wiltshire, and who had a taste for the marvellous.

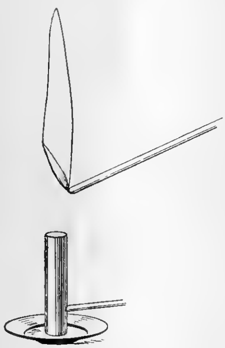
O. FISHER.

Harlton, Cambridge, October 19.

A Curious Flame.

THE following experiment with a Bunsen flame may interest some of your readers.

A Bunsen burner is lighted below and turned down so that the escaping gases will no longer burn at the upper end of the tube. The end of a glass rod is placed in the stream of gas and a lighted taper applied to it. The gas now burns steadily and the flame takes the form of a finger-stall attached by one point to the rod. A little adjustment of the gas supply may be required. A glass tube filled with water will not serve, which suggests that the rod must have a temperature of more than 100° C. Wires of any common metal may be used instead of the glass rod. It is a beautiful experiment.



The above came under my notice about six months ago when experimenting with flames, and I can find no reference to it in any book or journal. Perhaps some of your readers can give me information.

L. L. GARBUTT.

Winchester College, October 20.

THE LONDON FOG INQUIRY.

THE action of the County Council of London in devoting a sum of money for the purpose of aiding the Meteorological Council in making an inquiry into the occurrence and distribution of fogs in the London district has attracted public attention to an undertaking which is in itself of a very unambitious character. The discomforts and dangers of a London fog are indeed a loud challenge to the scientific and practical intelligence of Londoners, but what is aimed at in the present case is not any heroic attempt to deliver London from its insidious enemy, but the collection of information as to the best mode of attacking the purely meteorological question of local forecasts. In the language of the hour, it is a scouting expedition and not an attack in force.

Whether such a preliminary inquiry will of itself yield results that are either novel or valuable is still to some extent a matter of opinion. It originated in a request from the electric lighting authorities of several districts to be supplied, for obvious reasons, with forecasts or warnings from the Meteorological Office of the probable occurrence of serious fogs. Very much is already known about fogs. Apart from the special investigations of Dr. Russell and others, the students of weather maps are quite familiar with the general meteorological conditions under which fogs are likely, and recognise even more easily the conditions when they are unlikely. Besides this more or less technical knowledge, there is a large and increasing store of experience of fogs amongst the millions of dwellers in the London district. From recent circumstances I am able to say that he who would select an abode in London can obtain much curious information on the subject from friends, scientific and otherwise. It may take the form of testimony as to the relative prevalence of fog in other people's localities or its intolerable prevalence in his own, according to the temperament of the witness. It must, perhaps, be allowed that it is a rash undertaking to controvert the statement that the phenomena of London's fogs are well known.

Yet when one is brought face to face with the practical question, "Can you give us an hour's warning of the approach of a fog in any particular district?" one is driven to realise that, after all, the abundant knowledge based on the prolonged experience of many observers lacks coordination. If conditions are favourable for the occurrence of fog, which part of London will be the first to experience it? and at what rate will it spread or move to other parts? and where will it be most dense? Will it begin on the river and gradually extend to the heights, as a sea fog pours over the land? or will the heights first cover themselves with mist rolling down to the valleys? or if some locality is specially favoured as compared with others, by what numerical or percentage estimate should the advantage be estimated?

Statistical answers to these questions are clearly within reach. One year's experience will give no final statistical results, but it may at least give an indication of the possibility and prospect of obtaining such results. Some preliminary understanding must be arrived at as to the method of describing the experience of the different observers. There are fogs of many colours and of diverse character and density; some are on the surface, others, which do not come so low even as the tops of buildings, produce at noonday the darkness of night. It may be assumed that these differences of type, as well as differences of distribution, are not entirely capricious, but are related to some specific difference in the meteorological conditions, general or local, the local topography and conditions of the surface, or the local geology. All these things can also be ascertained, but whether the differences are sufficiently marked as to be recognisable in individual cases and to form a basis for forecast work is a question which, with all deference to the opinion of those who regard the phenomena of fogs as known, is worthy of investigation. Nor is it even easy, when one considers the difficulty of securing uniformity of convention among observers and uniformity of exposure of thermometers and other instruments. It is a question that requires to be approached, if confusion is to be avoided, with the intelligence of trained scientific scepticism.

The County Council, while authorising the organisation of observations at the fire stations by the staff of the fire brigade and possibly at other institutions under the control of the Council, have assigned to the Meteorological Office the responsibility for the conduct of the investigation and for providing all necessary instruments. The Office is also expected to make arrangements for observations outside the administrative County of London. The organisation of the details of such cooperation is not without its difficulties, but the cordiality with which the County Council has expressed its desire to cooperate is a weighty element in favour of the success of the attempt. It is obvious that without such cooperation the organisation of an efficient system of volunteer observations would be a matter of great labour and prolonged delay.

I have been careful to indicate the limitation of the immediate scope of the present inquiry to the collation of local observations of fog, and perhaps of temperature of air and water, with other local data and the general meteorological conditions. This is mainly a matter of appropriate organisation. There are, however, some physical aspects of the formation of vapour in the atmosphere which may be of service as a guide to the classification of the conditions of distribution of fog. In the forefront I would place the question as to what is the source of supply of the water which is the main constituent of those fogs which are not simply wreaths of smoke. Does the water come from the ground on which the fog lies? or the air in contact with it? or from some higher or more distant region? It is a matter of common observation that a surface of relatively hot water covers itself with drifting clouds of so-called steam. There are doubtless surface fogs which correspond to this condition, though when the evaporation is very rapid there may be, as Mr. C. T. R. Wilson has shown, a clear layer immediately in contact with the water surface. Fogs which have their origin in this mixture of the rising vapour with cooler air may be called "steaming water fogs." On the other hand, if any surface is sufficiently cold the absorption of heat from the air in contact with it may cause condensation in the air close to the surface, and fogs arising in this way may be called, for the sake of brevity, "cold-surface fogs." Vigorous radiation such as takes place on a clear night from grass may cause a fog of this character, and in regard to the persistence of a fog under these circumstances the transparency, or rather translucence, of fog for radiation is an important but not well-known factor. In these cases the source of the water supply is easily identified as being the water surface in the one case and the air in contact with the surface in the other.

Clouds, consisting of more or less detached masses of fog formed in either of these two ways, may drift like the steam from a locomotive or a sea fog over land, and a fog may thus visit a locality which has had no share in supplying the water. There is, moreover, another possibility which may be connected with the question as to why fogs are more prevalent in winter than in summer, in spite of the fact that the store of moisture in the air is larger and changes of temperature are more pronounced in the warmer months. Rain has been defined as a falling cloud which reaches the surface before the evaporation of the globules is complete. The rate of fall depends on the size of the particles, but in still atmosphere even the smallest particles make their way downward. In summer the falling cloud may consist of anything between a thunder shower and drizzling rain. In winter, when the supply of moisture is less and, over towns, the supply of nuclei for condensation is greater, the counterpart of the summer drizzle may be so light as to be classed as fog or mist, and fall with extreme slowness. In this case the water supply comes from strata above the surface. There are certainly some fogs in which there seems to be a gradual deposit of moisture on horizontal surfaces, and not merely on specially cold surfaces. It is true that winter fogs are often associated with high barometric pressure, generally a fine weather association, but under similar conditions of pressure very light rainfalls on our eastern and northern coasts are sometimes experienced. Whether electrical conditions, which are exceptional in foggy weather, may account for the formation or accelerate the falling of the cloud in such circumstances I cannot say.

If we call this third form of fog, due either to the surface drifting or the downward descent of a cloud formed above the surface, a "cloud fog," we have altogether three forms—"steaming water fogs," "cold-surface fogs" and "cloud fogs." It is evident that, of these three, two depend upon local conditions which may possibly be identified, while the third is at least much more independent of local conditions and its incidence may be as capricious as the summer cloud.

The consideration of the observations from this point of view requires more than mere organisation. It involves a special knowledge of the physics of the atmosphere applied to observations of a somewhat special kind, and may need some appropriate apparatus. It is hoped that circumstances will allow the statistical investigation to be combined with the consideration of such physical questions as those which I have indicated; but the time for arrangement is short, and it is possible that the physical side of the investigation may have to wait for a more favourable opportunity. The primary consideration at present is the suitable organisation of trustworthy observations.

W. N. SHAW.

ALUMINIUM AND ITS USES.

THE number of metals available in large quantities for industrial purposes is so very small, that the successful introduction of a new one must be of the greatest interest. The affinity of aluminium for oxygen much exceeds that of iron at a red heat. Iron oxide is reduced by carbon at that temperature, while alumina cannot be reduced in this way except in the electric arc. And thus, though the ores of aluminium are more widely distributed even than those of iron, yet the former metal remained for long unknown, and until lately was comparatively rare.

About fifty years ago, the researches of Wöhler and Deville led to the latter's process for the production of aluminium on a commercial scale, in which the vapour of aluminium chloride was led over heated sodium. The price of the new metal fell rapidly, but was always high and dependent upon that of sodium.

In 1854, Bunsen and Deville showed independently that aluminium could be obtained by electrolysis from a bath containing the chlorides of both aluminium and sodium in a state of fusion, the latter chloride acting merely as a flux. But at that time the cost of electrical energy was prohibitive.

The first successful electrical process was that of Cowles, in which alumina is reduced by carbon in the electric furnace. It rapidly superseded the old chemical method, in spite of the reduction in the price of sodium by the Castner process, but had soon in its turn to give place to the processes of Hall and Héroult discovered in 1886 (though not successfully worked until some years later). In these, a bath of the fused fluorides of aluminium and sodium is employed. They occur naturally combined as cryolite; and serve, when melted, as a solvent for alumina, which by itself would, of course, be almost infusible. The alumina is electrolysed by a current introduced at a carbon anode, and further alumina is added as the metal collects at the other pole. The bath must be maintained at a red heat, and an electromotive force of somewhere about five volts is needed.

It is this process which has brought down the cost of aluminium so much of late. Other methods, as those of Blackmore and Gooch, depending upon the preparation and subsequent electrolysis of fused aluminium sulphide, are said to be yet more economical, the sulphide being much more readily decomposed than the oxide. But the saving in electrical energy does not yet seem to make up for the greater expense of working materials.

The cost of water-power, even in situations offering great natural advantages, cannot be indefinitely reduced, owing to the great capital outlay needed for hydraulic works. There is, then, little doubt that the present cost of aluminium, about eighteenpence a pound, represents roughly the lowest figure at which the Hall and Héroult processes can profitably be worked. With a density 30 per cent., and a conductivity 60 per cent. that of copper, pure aluminium conductors can transmit the same electrical energy over a given distance with only half the weight of metal. As an electrical conductor, therefore, aluminium at eighteenpence is equivalent to copper at ninepence a pound, or 84*l*. a ton, a figure considerably below what it lately reached.

It is curious to observe how entirely dependent the electrical engineering industry is upon the price and the conductivity of copper. The former largely determines the degree of success, or at all events the method of carrying out, of electrical power transmission schemes; while the latter, in conjunction with the permeability of iron, actually decides the scale upon which our electrical machinery must be built, since the output or effort for a given speed of running is always limited by the heating which occurs; and this, at full load, arises mainly from the imperfect electrical conductivity of copper.

Aluminium offers, it is true, no prospect of reduced size of our machinery, owing to its bulk (*diameter* nearly 30 per cent. greater than equivalent copper); but it will now always act as a check upon the artificial raising of the price of copper.

The high cost of insulating materials renders it unlikely that aluminium with its greater size will ever replace copper in insulated cables. And even as a bare conductor, it is doubtful what advantage in price (together with whatever saving may come from having wires only half as heavy to handle and support) will compensate for the many disadvantages as compared with hard-drawn copper—greater liability to corrosion, difficulty of making joints, less tensile strength (even of aluminium bronze), lack of uniform quality, greater surface exposed to the wind, greater unsightliness owing to size (for trolley wires), &c.

Still, the excessive price of copper which has obtained during the last two years, and indeed till a few months ago, has led to the putting down of between one and two thousand tons of bare aluminium conductors for electric-power transmission—chiefly in America, and for very high-tension, long-distance schemes—schemes, in fact, in which the cost of the lines represents the greatest proportion of the whole expenditure.

The experience as to the behaviour of aluminium already gained from these installations is very valuable, as may be gathered from a perusal of two recent papers—one read by Messrs. Perrine and Baum before the American Institution of Electrical Engineers, and the other by Mr. Kershaw before our own similar Institution. The former writers find that, owing to a large temperature change in the elastic constant, the true coefficient of expansion of the new metal is not applicable in calculations of stresses in suspended wires having a given sag, the apparent temperature effects being much less than those calculated. Again, in the latter paper it is suggested that aluminium will not weather so well in this country as in the drier climate of America. It would seem also as if, while good soldered joints are quite possible with the metal, only welded or "burnt" joints involving no solder are durable out-of-doors, the metal being so highly electropositive, and the alloys formed near soldered joints unstable. Mechanical joints are generally used in America. The McIntyre joint is made by slipping the ends into a flat aluminium sleeve, the whole being then twisted round twice or thrice. It is doubtful whether such joints retain their initial high conductivity, in view of experience with similar joints in telegraph work. As an electrical conductor, then, it is only in those rare cases where conducting power for a given weight is wanted, *irrespective of volume*, that aluminium is without question the best material to use.

For structural purposes, the new metal has up to the present proved a little disappointing. In the first place, the pure metal is useless, being too soft. This, however, was to be expected. Pure iron is also soft. The alloys with copper up to a density of 3 include some which seem fairly strong; but the fact that cycle frames are still made of steel shows that, where strength and lightness are required together, and cost is not of great moment, steel can still hold its own, apart from its relative cheapness. No doubt, however, there is yet much to be learnt about the metallurgy of the alloys with copper, and with other elements also—nickel, tin, magnesium, &c.

A considerable demand for aluminium has grown up in connection with the manufacture of a great variety of small articles, instruments, &c. The most important uses of the metal from a commercial point of view are based upon the activity of its reactions at a high temperature. Added in small quantities to molten iron just before a cast is made, the metal is rendered more fluid and the quality of the casting thereby improved.[1] This result appears to be due to the reduction by the aluminium of any iron oxide which may be present, and to the raising of temperature of the iron itself by the heat of the action. It was stated by Swan, in a recent presidential address in Glasgow, that this use of the metal formed one of the chief outlets for the 6000 odd tons of aluminium which were manufactured last year.

The Goldschmidt process, by which the most intense heat can be produced in any required amount at a given point also depends upon the same fact, that aluminium can reduce iron oxide with energy to spare. A mixture of finely-divided aluminium and iron oxide, known as "thermit," can be ignited by a suitable fuse, and results in a quantity of molten iron heated far above the melting-point and protected from combustion by a layer of alumina. This iron, being so very greatly superheated, will serve for a variety of purposes, and its quality can be varied as required by suitable additions to the "thermit." This process was lately described and demonstrated at the Royal Institution by Roberts-Austen,[1] to whom, indeed, it is largely due. It has been applied to the welding of rail joints in position for electric traction, and to the repairing of broken and of faulty steel castings. The process has, in fact, many of the possibilities of the electric furnace, without the drawback of being dependent upon a fixed and costly electrical installation.

THE OCTOBER ORIONIDS.

IN many previous years the Orionid radiant has been well defined at a point very close to, if not coinciding with, the position of the star ν Orionis (mag. $4\frac{1}{2}$). The shower was very successfully observed by Prof. A. S. Herschel on about October 18–20 in the years 1864, 1865 and 1867, when the centre of divergence was found to be at $90^\circ + 15^\circ$. A number of observations were obtained at Bristol in 1877, 1879, 1887 and other years, and the radiant derived from them was at $91^\circ + 15^\circ$. The meteors of this shower belong to the swifter class, and they leave streaks which enable their directions of flight to be so correctly noted that the centre of emanation not only appears sharply defined, but can be very accurately located. The streaks frequently linger for two or three seconds and will sometimes very perceptibly brighten up after the heads of the meteors have vanished.

The observations in 1900 and 1901 made at Bristol show that the true Orionids were feebly represented and that, in fact, the annual shower-meteors from the old position at ν Orionis had been supplanted by a more active radiant of Geminids agreeing in place with the star ξ Geminorum (mag. $3\frac{1}{2}$). On October 23–27, 1900, and October 20, 1901, I recorded about twice as many meteors from $100^\circ + 13^\circ$ as from $91^\circ + 15^\circ$. The observations were not very numerous, but had they been far more complete there is no reason to suppose that the conclusions would have been materially affected.

The difference of 9° in the positions of the radiants at ν and ξ Orionis is sufficiently large to be immediately detected by meteoric observers though their materials are merely eye estimations. The latter are, however, unusually trustworthy, not only in the case of the Orionid display, but also in regard to some of its bordering and contemporary showers which furnish similar objects. The flash of a meteor's head as it darts rapidly along in a state of combustion attracts the eye to the point of appearance, and the streak which immediately glows along the path enables the observer to fix the apparent direction of flight with almost instrumental precision.

In the *Monthly Notices* for December 1895 (vol. lvi. p. 74) I mentioned the γ Geminids as one of the most prominent companion radiants of the Orionids and gave the mean position of the centre as 97°·1 + 15°·2 from thirteen observations by various observers. In the "General Catalogue of Radiant Points" (*Memoirs* R.A.S., vol. liii.) this shower forms No. lxxix. and the radiant is given at 96°·6 + 16°·5, based on nineteen observations. But there is now reason to believe that these positions are two or three degrees north of the correct place and that instead of corresponding with the star γ Geminorum it really agrees with ξ Geminorum. Certainly in 1900 and 1901 the most conspicuous shower of rapid streak-leaving meteors was directed from 100° + 13°, the position of the star ξ Geminorum for January 1901 being α = 6h. 39m. 44·0s., δ = 13° 0′ 9″·1 +.

It will be interesting to watch future returns of the October meteors in order to ascertain whether the formerly strong shower at ν Orionis has only been temporarily weak during the few past years or whether it has finally withdrawn in favour of its easterly companion radiant at ξ Geminorum. Possibly the swarm of Orionids has been recently disturbed by planetary attraction and the node displaced sufficiently to bring about a change of 9° in the radiant. If so, the principal meteoric display of October must henceforth be known as Geminids instead of Orionids. But the more probable supposition appears to be that the Orionids have been very scantily distributed along those parts of their orbit traversed by the earth in late years, whereas the neighbouring shower in Gemini has been so much stronger than usual as to form the principal display of the epoch. The Orionid system used to present itself with considerable regularity like the August Perseids, though it exhibited variations of strength in part no doubt attributable to the different atmospheric conditions prevailing, to the position and age of the moon and to other circumstances capable of affecting the visible aspect of the stream.

W. F. DENNING.

ARMOUR-CLAD WHALES.

AMONG the many wonderful palæontological discoveries that have startled the scientific world during the last few years, none, perhaps, is more unexpected than the revelation that the ancestral whales were protected from attack by a bony armour analogous to that with which the armadillos of South America are covered. Scarcely less marvellous is the fact that vestiges of this ancient coat of mail are still borne by such familiar cetaceans as the porpoise and its near relative the Japanese porpoise (*Neophocaena phocaenoides*), the latter species being distinguished by the absence of a back-fin. That creatures like the modern pelagic whales and porpoises, or even the river dolphins, could ever have been invested with a complete bony armour is, of course, an absolute impossibility. The rigidity of such a panoply would have interfered far too much with the mobility of their supple bodies, while its weight would have impaired their buoyancy. Consequently it is necessary to assume that in even the earlier representatives of these types the armour must have been in a condition of degradation and elimination, so that we must go back to still earlier forms to find it in its full development. As every one knows nowadays, whales and dolphins trace their ancestry to land animals, and it appears highly likely that when such ancestral creatures began to take to an amphibious life on the sea-shore, or at the mouth of a large river, they may have developed a dermal armour which would serve to protect them alike from the breakers and from the attacks of sharks and other marine monsters. For the idea that the terrestrial ancestors of the cetaceans were clad in armour cannot for a moment be entertained, since the primitive mammals were not so protected and the American armadillos afford an instance of the development *de novo* of such a bony panoply at a comparatively recent epoch.

Years ago the late Dr. H. Burmeister described a porpoise from Argentina as *Phocaena spinipinnis*, on account of its possessing a number of spiny tubercles embedded in the skin in the neighbourhood of the back-fin as well as on the fin itself. "Some small spines," he writes, "begin in the middle of the back, at the distance of 25 centimetres in front of the fin, as a single line of moderate spines; but soon another line begins on each side, so that in the beginning of the fin there are already three lines of spines. These three lines are continued over the whole rounded anterior margin of the fin and are augmented on both sides by other small spines irregularly scattered, so that the whole number of lines of spines in the middle of the fin is five." In a section of the skin of the back-fin the tubercles are distinctly seen, many of them being double.

Similar tubercles were described on the back-fin of a porpoise taken in the Thames in 1865; and quite recently a row of no less than twenty-five well-developed tubercles has been detected on the front edge of the back-fin of a fœtal porpoise, these tubercles being nearly white and thus showing up in marked contrast to the dark-coloured skin. Even more distinct are the tubercles in the skin of the finless back of the Japanese porpoise, where they form several rows of polygonal plates.

In a fossil porpoise (*Delphinopsis freyeri*) from the middle Tertiary deposits of Radoboj in Croatia, the tubercles were still more strongly developed, and formed a series of regularly arranged and parallel rows in the neighbourhood of the back-fin. They clearly indicate one step from the modern porpoises in the direction of a species provided with a functional bony armour in this region of the body. Between the extinct Croatian porpoise and the much more ancient whale known as *Zeuglodon*, some part of whose body was protected by a bony armour as solid as that of the giant extinct relatives of the modern armadillos, the intermediate links are at present unknown, although they may turn up any day. *Zeuglodon* was first discovered in the early Tertiary strata of the United States, but its remains have subsequently been obtained from the equivalent deposits of Egypt and elsewhere, and in early times it was probably the dominant cetacean of the world. Years ago there were discovered with the bones of the internal skeleton of this whale a number of bony plates which originally formed a dermal armour; although they were regarded as belonging to a species of leathery turtle and as having nothing to do with the whale.

But in microscopic structure, as well as in their arrangement, these polygonal bony plates differ altogether from the armour of the leathery turtle; while their structure is generally similar to the undoubted bones of *Zeuglodon* with which they are found in association. Moreover, a fragment covered on one side with armour of this type has been discovered which cannot, apparently, be any part of the shell of a turtle, but which may well be the back-fin of *Zeuglodon*. And as the aforesaid bony tubercles of the porpoises are always found on or near the back-fin, it is a safe assumption that in *Zeuglodon* the entire dorsal fin, as well as some portion of the back, was covered with a complete tessellated armour of bony plates.

The majority of the living toothed whales (inclusive of porpoises and dolphins) are furnished with a dorsal fin, and it is therefore reasonable to suppose (apart from the evidence of the specimen just referred to) that *Zeuglodon* was similarly provided; and if this be so, that cetacean was evidently a pelagic creature. For the function of a dorsal fin is to act as a kind of keel in maintaining the balance of the body, this appendage being most developed in purely pelagic cetaceans like the killer, while in littoral or fluviatile forms, such as the narwhal, the white whale and the Japanese porpoise, it is either small or wanting. It is, further, noticeable that cetaceans with pointed muzzles (of which *Zeuglodon* is one) nearly always have a larger back-fin than those in which the muzzle is short and rounded. In the whalebone bones, among which the dorsal fin is either small or wanting, its function may be discharged by the keel on the middle of the upper jaw, or, owing to corporeal bulk, no such function is required at all.

If, then, we are right in regarding *Zeuglodon* as a pelagic cetacean, it is evident that it could not have been completely armoured, but that such armour as it retained was merely a survival from a fully armoured non-pelagic ancestor. For it is almost impossible to believe that the ancestral cetacean was not invested in a complete panoply, at least on the dorsal region.

The whole argument is tersely summed up as follows by Dr. O. Abel (*Beitr. Pal. Öster.-Ung.*, vol. xiii. pt. 4, 1901), to whom naturalists are indebted for these interesting researches.

In their earliest stage of development the toothed whales were fully armoured. The object of the armour was as a defence against enemies, such as sharks, such an armour being also very valuable to animals exposed to the force of a strong surf on rocky shores. As the creatures took more and more to an aquatic life, the acquisition of greater speed would be of greater value to them, and this would be accomplished by diminishing the specific gravity and friction of the body, the shortening of the extremities and the development of a caudal fin to serve as the sole instrument of locomotion.

Accordingly the armour would very soon be lost by the pelagic cetaceans in order to diminish friction and lighten the specific gravity. Only among certain types, which diverged at an early epoch from the ancestral stock and took to a fluviatile or estuarine life, did vestiges of the armour persist, while the dorsal fin remained undeveloped (*Neophocaena*). That in this form, as well as in the closely allied true porpoises (*Phocaena*), we have the most primitive type of living toothed whales, is confirmed by the nature of their dentition, as well as by the circumstance that in this group alone the premaxilla is toothed. The relation of the interparietal to the parietals is likewise confirmatory of the antiquity of the porpoises.

As many of our readers are aware, *Zeuglodon* differs from modern cetaceans by the characters of its teeth, those of the lateral series being double-rooted and having compressed and serrated crowns, distantly recalling those of the leopard-seal. Between *Zeuglodon* and the shark-toothed dolphins (*Squalodon*) the gap is very great, but still one which might readily be bridged were the missing links forthcoming; and as it is the molars of the one type seem derivable from those of the other. In *Squalodon* the molars alone retain the double-rooted character of *Zeuglodon*, and a transition from the former, in respect of tooth characters, to the modern dolphins and porpoises is afforded by *Saurodelphis*, of the Argentine Pliocene, in which the roots of the teeth, although single, are elongated antero-posteriorly and thus display clear evidence of their original duality. By Dr. Abel, *Saurodelphis* is indeed regarded as occupying the middle position between *Squalodon* and the modern dolphins; but the porpoises are considered to form a side branch which diverged from the main stem at an earlier date than the appearance of the genus first named.

In conclusion, it may be mentioned that modern investigations tend to connect the ancestral toothed whales with the Carnivora, and in no wise support Sir William Flower's favourite idea that these cetaceans trace their descent from early Ungulates. R. L.

TIBET AND CHINESE TURKESTAN.[1]

THE geographical area illustrated by Captain Deasy's book lies in one of the most remote and, at the same time, one of the most interesting regions (regarded politically) in the whole continent of Asia.

British India (represented by Kashmir) lies south and west of it; to the north, north-east and east stretch the shadowy outlines of the "new dominion" of China and the lofty uplands of Tibet; Russia looms large to the north-west; and a long thin slice of Afghanistan reaching out an arm eastwards nearly touches it on the western border. It is an area which bristles with the physical difficulties presented by a vast array of gigantic mountain chains interspersed with flat spaces of desolate upland and salt marsh, and it is an area which those high authorities who regulate international boundaries will sooner or later find it necessary to discuss in close detail; for hereabouts exists one of the nebulous corners of the Empire. Boundary commissions have come and gone, but they have still left undecided the question how far China extends south, or Kashmir north; nor can anyone give final shape to Russia's line of boundary where she leaves Afghanistan and spreads eastward towards China. Consequently Captain Deasy's geographical work, and the interesting book in which it is described, possess a value which can only be regarded as unique. It is only by the light of his excellent map that any conclusions can be drawn as to the physical nature of this rugged no man's land, and only by the light of his description of it can any value be assigned to its apparently desolate hills and valleys. It is no small achievement for a cavalry officer to carry the principles of scouting on scientific geographical lines into such a field of difficulty and desolation as is presented by the buttressed spurs of the Kuen Lun and the Muztagh ranges.

Captain Deasy has set a most excellent example to aspiring travellers in remote regions—an example which has been lately emphasised strongly by the methods of the great traveller Sven Hedin—in the careful preparations which he made for the scientific prosecution of his work. He is not merely an observer. He has proved himself to be an advanced geographical surveyor. He first armed himself with all available data on which to base his exploration, and then attached himself to the best of all possible schools of instruction in order to learn how to make the best use of it. The result is a map which is probably quite accurate enough to take its place as the standard geographical reference for all that part of High Asia with which it deals, and which must be regarded as the most important result of his combined literary and field efforts. His observations were all worked out by the professional computers of the Indian Survey, and the results are tabulated and a record made of their value, in the appendix to his book; so that the indefinite haze which usually envelops similar records by less careful workmen is absent in Captain Deasy's work, and we know precisely what to make of it. The book, which embraces the narrative of his travels (illustrated by an excellent series of photographs), is written with the traditional modesty of a soldier, and gives a faithful and graphic account of the extraordinary difficulties which beset the travellers in the Tibetan borderland. There is no occasion to exaggerate these difficulties, or to draw on the imagination for thrilling episodes and situations. They are formidable enough to tax all the resources of ability and determination which the best of explorers may have at his command. If Captain Deasy's own description of them hardly does justice to the extraordinary obstructiveness of the ugly passes of the gigantic Tibetan ranges, his illustrations at least do not fail to make it plain. It is almost

[1] "Tibet and Chinese Turkestan." By Captain Deasy. Pp. xvi + 420. (London: T. Fisher Unwin, 1901.) Price 21s.

inconceivable to anyone who has not witnessed the experiment, that such passes should be negotiable at all, even if the gymnastic capacity possessed by the yak or by the coarse-bred and clumsy Yarkandi pony be duly appreciated.

Captain Deasy's narrative is a plain and simple record of a very remarkable series of explorations. It cannot fail to be interesting to all who love adventure, or who discern a future of political difficulty looming on the borders of Tibet. It is interesting to the geographer for many reasons, not only because it illustrates certain methods which should be adopted by every modern scientific traveller in Asia, but because it solves many an old geographical problem and suggests one or two new ones. Amongst other important determinations, that of the altitude of the Muztagh-Ata of Sven Hedin (which is now definitely ascertained to be 24,000 feet above sea-level) fixes the height of the highest peak north of the Himalaya. T. H. H.

FIG. 1.—Scene in the Takla Makan.

NOTES.

THE president of the Board of Education has appointed Prof. Hugh L. Callendar, F.R.S., to the professorship of physics in the Royal College of Science, South Kensington, in succession to Prof. Rücker, who, as already announced, has become principal of the University of London.

THE Duke of Devonshire has suggested a reason for the tentative way in which the problem of our educational organisation has been attacked. In opening the new Central Technical School at Liverpool on Saturday he placed the responsibility for the present state of affairs upon educational authorities, religious and political bodies, employers, workmen, parents and other representatives of the community, because "the only source of strength by which the Government could hope to surmount the difficulties would be the conviction of public opinion of the importance of education itself and the necessity for its extension and organisation." He anticipated the criticism that must be passed upon such a statement by saying "He would probably be told he was whistling for a wind; that he was asking for an expression of public opinion which would guide the Government in forming either large or small proposals on the subject of education. He did not altogether resent the imputation." It is clear from this that our Ministers acknowledge that they are not leaders so far as education is concerned. The Lord President's reference to whistling for a wind is unhappy when other nations are going full speed ahead under steam. Dr. Macnamara puts the case very forcibly in a letter to Tuesday's *Times*, where he remarks that what the British people ought to give the Government is, not a breeze, but a tornado. Something should be done to bring about this storm and so waken our rulers into activity. The education question is too important to be permitted to drift along as it has done; and even now it will be a hard task to make up the leeway. Our educational deficiencies are obvious to everyone who has given consideration to the subject. Report after report has been published showing that we only occupy a fifth-rate position when considered from the point of view of provision made to equip people for the industrial struggles of the future. The Government knows this, but it can scarcely appreciate the fact that national progress depends upon intellectual equipment, or it would hasten to do something to organise and extend our educational system.

THE following is the text of the address of congratulation presented to Prof. Virchow, on the occasion of his eightieth birthday, by those members of the Anthropological Section of the British Association who were present at the recent Glasgow meeting:—"British Association for the Advancement of Science: the Section of Anthropology to Prof. Rudolph Virchow:—It seldom falls to the lot of one man to establish a position, as you have done, as a leader in two great branches of science. Throughout the world you are generally recognised as the founder of modern pathology, whilst in the domain of anthropology your services have been hardly less remarkable. Whenever anthropologists meet together, your name is mentioned with the respect a d reverence that are due to a great master. At the present moment the British Association for the Advancement of Science is holding its annual meeting in Glasgow, and the members of the Anthropological Section, aware that you celebrate your eightieth birthday on October 14, desire to convey to you their affectionate greetings, and to express the hope that you may be spared to add yet further to the indebtedness which they owe to you as a worker in the same field. Signed on behalf of the committee of the Anthropological Section, D. J. Cunningham, president, J. L. Myers, recorder. Glasgow, September 11, 1901." The address, richly engrossed, was presented personally to Prof. Virchow by Lord Lister in the course of the celebration ceremony at Berlin.

To remove any misapprehension as to his opinion upon the result of M. Santos Dumont's recent aërial performance, M. Deutsch has written him a letter stating that he considers the trip to have been completely successful and that the prize has been won. M. Deutsch sent M. Santos Dumont at the same time the sum of 1000*l.*, which the latter has handed to the Prefect of Police for distribution among the poor of Paris. The committee's decision concerning the prize of 4000*l.* has not yet been announced.

SIR H. TRUEMAN WOOD will deliver the next Christmas Juvenile Lectures at the Society of Arts, the subject being "Photography and its Applications." The idea will be to show in what a large number of cases photography has been applied to scientific observation, and how varied are the applications. The subject is an interesting one and ought to prove very attractive. The dates of the lectures are January 1 and 8.

SIR HIRAM S. MAXIM confirms the observation mentioned in our issue of October 17 (p. 607) of the attraction which certain sounds have for mosquitoes. Writing to the *Times*, he states that one of the electric lamps which he put up at Saratoga Springs, New York, in 1878, emitted a musical note; or rather the note proceeded from the box containing the dynamo machine under the lamp. One evening whilst examining the lamp he found that everything in the immediate vicinity was covered with small insects. They did not appear to be attempting to get into the globe, but into the box that was giving out the musical note. A close examination of these insects showed that they were all male mosquitoes. Although there were certainly 200 times as many female mosquitoes on the ground as males, not a single female mosquito was found to have been attracted in the least by the sound. Sir Hiram Maxim remarks that "when the lamps were started in the beginning of the evening every male mosquito would at once turn in the direction of the lamp, and, as it were, face the music, and then fly off in the direction from which the sound proceeded. It then occurred to me that the two little feathers on the head of the male mosquito acted as ears, that they vibrated in unison with the music of the lamp, and as the pitch of the note was almost identical with the buzzing of the female mosquito the male took the music to be the buzzing of the female."

PROF. E. RAY LANKESTER has been elected a corresponding member of the Royal Society of Sciences of Göttingen.

THE exhibits of the German Chemical Industry Section at the Paris Exposition, valued at 30,000*l.*, have, it is said, been presented to the Technological Institute of the Berlin University.

MR. G. W. DE TUNZELMANN has been appointed editor of *Science Abstracts* in succession to Mr. W. R. Cooper, and will take over the duties of the office on January 1 next.

A SICILIAN agricultural exhibition is, according to a Consular Report, to be held at Palermo from March to May next. There will be a class for international agricultural machinery.

THE new specimens added to the Museum of Anatomy and Pathology at University College, Gower Street, will be on view until November 2.

THE Bradshaw lecture will be given before the Royal College of Physicians on November 5 at 5 p.m., by Dr. J. S. Bury. The subject will be "Prognosis in Relation to Disease of the Nervous System."

On Tuesday next, November 5, the president of the Institution of Civil Engineers will deliver his inaugural address, distribute the council's awards, and hold a reception. The meeting will take place at 8 p.m.

THE Lettsomian lectures of the Medical Society of London will be delivered on February 17 and March 3 and 17 next, at 9 p.m., by Mr. A. Pearce Gould, who will take as his subject "Certain Diseases of the Blood Vessels." The annual oration will be delivered on May 26 by Dr. Stephen Mackenzie.

ACCORDING to the *British Medical Journal*, Surgeon-Gen. Wyman, of the U.S. Marine Hospital Service, proposes to establish an institute for the study of yellow fever. The work will be divided into four departments or sections, viz., history and statistics, etiology, transmission, quarantine and treatment. An executive board is to have general charge of the investigations and the publication of reports.

A DETAILED account of the relationship between mosquitoes and the spread of yellow fever is given in the Paris *Bulletin Medical* by Dr. H. de Gouvèa, who studied the subject for many years in Brazil. Dr. Gouvèa shows that the conditions of propagation of the disease have always been such as to fulfil the requirements of the mosquito hypothesis, and to afford abundant indirect evidence in favour of the belief which has now been reached by more direct methods. In conclusion, he formulates a series of propositions—namely, that yellow fever is never conveyed by either direct or indirect contagion; that the actual cause of it, at present unknown, will in all probability be discovered in the human blood; that it is diffused only by the agency of the mosquito, *Culex toeniatus* or *fasciatus*; and that immunity from it may be secured by the destruction of these insects, or by avoidance of their haunts during the periods of their activity.

A DIFFICULTY has arisen concerning the site on which the new Pasteur statue in Paris shall be erected. The use of a space in the Square Médicis in the Quartier Latin has been granted, but this spot is being tunnelled for a railway, and it is feared, in consequence, that the statue may be too weighty for it. Other places, such as the Place du Panthéon, the Place de la Sorbonne, and the entrance of the Avenue de l'Observatoire, are under consideration.

A COMMITTEE of the Association of Chambers of Commerce meeting recently unanimously adopted the following resolutions:—"(1) That, after considering various suggestions, this committee is unanimously of opinion that the Chambers should unite in urging upon the Government the compulsory adoption of the metrical system of weights and measures, leaving matters of detail to be considered later. (2) That the committee is unanimously of opinion that a British decimal system of coinage must be on the basis of retaining the sovereign, with the florin as a unit, divided into a hundred cents or farthings. (3) The committee recommends that there should be nickel coins of five and ten cents, and bronze coins of one, two and four cents or farthings."

MEETINGS of the committee appointed by the Board of Trade to inquire and report as to the best means by which the State or local authorities can assist scientific research as applied to problems affecting the fisheries of Great Britain and Ireland took place on Tuesday, Wednesday and Thursday of last week for the purpose of taking evidence. Sir Herbert Maxwell, M.P., presided. Dr. T. Wemyss Fulton, scientific superintendent to the Scottish Fishery Board, and Mr. E. W. L. Holt, scientific adviser to the fisheries branch of the Department of Agriculture, &c., Ireland, were examined, and Mr. G. C. Bompas and Prof. G. B. Howes gave evidence with regard to the Buckland fish collection at South Kensington. Prof. E. Ray Lankester, the president, and Mr. E. J. Allen, the director, of the Marine Biological Association, and Mr. R. A. Dawson, superintendent under the Lancashire and Western Sea Fisheries Committee, also attended. Prof. Herdman, who is a member of the committee, submitted a scheme for fishery investigations in the Irish Sea, and the committee adjourned till December 3.

MR. J. STIRLING, Government Geologist, &c., Victoria, is to lecture at the Imperial Institute on November 18, on "Brown Coal Beds of Victoria, their Characters, Extent and Commercial value"; on December 9 Mr. D. Hutcheon, chief veterinary surgeon for Cape Colony, is to speak on "Agricultural Prospects of Cape Colony," and on December 16 Mr. H. N. Ridley, director of the Botanic Gardens, Singapore, will deliver an address on "The Economic Resources of the Straits Settlements and the Malay Peninsula." All the meetings will take place at 8.30 p.m.

THE provisional programme of the new session of the Royal Geographical Society has just been issued and contains the following arrangements:—November 11, the opening address by the president, and "The Uganda Protectorate, Ruwenzori and the Semliki Forest," by Sir Harry Johnston, K.C.B.; November 25, "Four Years' Travel and Survey in Persia," by Major Molesworth Sykes; December 9, "The Glaciers of Kanchinjunga," by Mr. Douglas W. Freshfield. Among the other papers which it is expected will be delivered during the session may be mentioned:—"A Journey from Omdurman to Mombasa by Lake Rudolf," by Major H. H. Austin, R.E.; "The Maldives," by Mr. J. Stanley Gardiner; "Journeys in Western China," by Dr. R. L. Jack; "The Influence of Geographical Conditions on History and Religion, with special reference to Asia Minor," by Prof. W. M. Ramsay; "An Expedition across Abyssinia, through Kaffa and the Region to the West and North," by Mr. Oscar Neumann; "Southwards on the Antarctic Ship *Discovery*," by Mr. George Murray, F.R.S., and Dr. H. R. Mill; "The Bedford Level and Experimental Demonstration of the Rotundity of the Earth," by Mr. H. Yule Oldham; "The Snows of Canada," by Dr. Vaughan Cornish; "A Journey from Quetta to Meshed by the new Nushki Trade Route," by the Earl of Ronaldshay; "The Ice Conditions of the Antarctic," by M. Henryk Arçtowski; "Methods and Appliances in the Teaching of Geography. Special Lecture for Teachers," by Mr. A. W. Andrews.

AN exhibition of scientific apparatus constructed by pupils and teachers of the London School Board for the purpose of teaching and illustrating some of the branches of experimental science is opened to-day at the Examination Hall, Victoria Embankment, and will remain open until Monday next. No charge is made for entrance, and the Board invite the inspection of the exhibits. Among the latter are to be found induction coils, telegraph instruments, motors, voltameters, galvanometers, Boyle's tubes, balances, and lantern and microscopic slides. There will also be shown dissections in a preservative spirit, such as a skate's ear, sheep's kidney, rabbit's lung, &c.

PROF. BASHFORD DEAN, says *Science*, has returned to Columbia University, bringing with him from the east an almost complete series of developmental stages of the Port Jackson shark, *Heterodontus japonicus*, a number of stages in the development of Chlamydoselachus, two new Myxinoids, a new Chimæra, together with a general zoological collection. During a visit to the Hokkaido (Yezo), he brought together several hundred specimens of Aino antiquities, which are now deposited in the American Museum of Natural History in New York. He also secured a collection of interesting glass sponges from the region of Misaki, which are also destined for the American Museum. Among other specimens are included a number illustrating artificial selection, a series of the highly specialised varieties of Japanese gold fishes, together with a number of the long-tailed fowls of Tosa, whose tail feathers sometimes reach the extraordinary length of fifteen feet. For the Columbia collection he obtained during a visit in southern Negros, P.I., a series of dissections of Nautilus, prepared from fresh material.

THE steam yacht *Antarctic* called at Falmouth on Saturday last and left on the same day with the members of the Swedish Antarctic Expedition on board. The leader of the expedition is Dr. Otto Nordenskjöld, whose work in Tierra del Fuego and Spitsbergen is well known to geographers. Other members are Captain Larsen; Dr. A. Ohlin and Mr. K. Anderson, zoologists; Mr. C. Skottsberg, botanist; Dr. G. Bodman, magnetician and hydrographer; and Dr. E. Ekelöf, medical officer and bacteriologist. From an article in the *Times* we learn that the vessel will proceed direct to Buenos Ayres, and thence by Staten Island (where the instruments will be compared with those of the Argentine scientific station) and the Falkland Islands, to the South Shetlands and the east coast of Graham Land (King Oscar Land), where, if a suitable spot for the winter quarters can be found, a station will be established for six or seven persons, under the command of Dr. Nordenskjöld himself, and observations carried out in harmony with those of the British and German expeditions. If, however, suitable quarters cannot be obtained, the winter station will be established somewhat further north. In any case, the ship, with two or three of the scientific observers, will return to South America and the Falkland Islands for the winter, after the best possible use has been made of the Antarctic summer.

A SHORT account of Antarctic exploration, and of the problems which still await solution by systematic observations in South Polar regions, is contributed to the October *Quarterly Review*. The German and British ships, the *Gauss* and the *Discovery*, have each been described as the best which have ever left on voyages of discovery, but the *Quarterly* reviewer demurs to this estimate, and remarks that Admiral Makaroff regards both the vessels as at least half a century behind the times. A steel ship like the great icebreaker *Ermack* is suggested as more serviceable than wooden vessels. "All who have inspected the *Ermack*, or have made a voyage in her, will probably admit that she is the most powerful and efficient vessel afloat for exploration, and the best equipped and most convenient for scientific observation and research. Should the Tzar send this splendid ship to the Antarctic seas next season her operations would most certainly result in large additions to knowledge in directions which cannot be attempted by the *Discovery* and the *Gauss*."

FROM the point of view of modern shipbuilding, the opinion expressed in the foregoing note upon the *Discovery* as a ship for scientific exploration is probably correct, but for obvious reasons it was impossible to design and build a vessel regardless of expense. From despatches just received by Sir Clements Markham from the Cape, it appears that the *Discovery* must be accounted a poor sailer, though she has proved to be a good sea boat. Her coal consumption is, however, disappointing, the economy of the engines being less than was expected. The ship leaked from causes which can no doubt be obviated, but the defect has necessitated clearing the holds to construct floors with an ample bilge space beneath, so that the provision cases be preserved from injury. These facts accentuate the importance of providing a relief ship to communicate with the *Discovery* at the end of the first winter, to take out coals and stores, and to render assistance in other ways. A strong appeal is to be made to supplement the funds already subscribed for this purpose. The sum of 6680*l*. has been obtained, but a further amount of 10,000*l*. is required, and this should be secured without delay.

A STRIKING testimony as to the value of Dr. Calmette's antivenene is to be found in an extract from a report by the medical officer on an Indian railway line which the current issue of the *Lancet* contains. "On the night of the 23rd [of August] I was called," says the medical man in question, "to see a coolie woman who had been bitten by a large snake supposed to be a cobra. She was said to have been bitten at about 7 p.m. and I did not see her till two hours later. She was then practically moribund, the throat paralysed, and consciousness completely lost. All the symptoms of poisoning by colubrine venom were well marked. I injected a full dose of Dr. Calmette's antivenene, but was not sanguine as to the result, the patient's condition being apparently hopeless. The effect of the remedy was marvellous; consciousness returned in fifteen minutes, and I was so encouraged by the result of the first injection that I decided to give another dose of the serum. It acted like magic and within three hours of the first injection the patient was well."

WE have received from Signor Palazzo, director of the Italian Meteorological Service, an account of the organisation of special stations for the study of hail and thunder storms and for carrying on further experiments as to the possibility of dispersing thunder clouds by gun firing. Although scientific men are very sceptical about the efficacy of the practice, the majority of Italian agriculturists are very enthusiastic in the matter, and the Government has consequently voted 10,000 lire for the establishment of two shooting stations in the most suitable localities and has provided them with the most sensitive instruments for predicting the advance of the storms, and with means for tracing their course and the amount of damage caused. Up to the present time the results obtained are contradictory; in some cases the firing appears to have had a favourable effect, while in others the firing apparatus itself has been choked by the falling hail. The inquiry will, at all events, be useful in throwing light upon the propagation and characteristics of thunderstorms.

THE twenty-third annual report of the Deutsche Seewarte, for the year 1900, shows that the subject of maritime meteorology has been prosecuted with increased activity; 75 complete logbooks were received from the Navy and 472 from the mercantile marine, in addition to which 299 abstract logs containing less complete observations were received. The consulates in various parts of the world, including several in this country, act as agencies for meteorological purposes. The observations are published in the form of tabular results referring to ten-degree squares, or districts of the ocean, and are utilised in the construction of the daily synoptic weather charts of the North Atlantic. The department dealing with weather telegraphy is also very active, and has made great endeavours to improve the service by the introduction of direct interchange of reports made at 7h. instead of 8h. a.m., a practice which is being followed by most countries, whereby weather information is disseminated earlier than before, with a consequent increase of utility. In this matter Dr. Neumayer has been very ably supported by Dr. van Bebber, the superintendent of the section engaged in weather prediction.

MANY attempts have been made to generalise the methods of "casting out" the nines or elevens so as to obtain in a simple form the criterion of divisibility of high numbers by factors other than 9 or 11. For example, we have the well-known test for divisibility by 7 or 13 which consists in pointing the given number off in thousands and subtracting the sum of the numbers in one set of alternate groups from the sum of those in the other set. Such generalisations date as far back as a paper in the works of Blaise Pascal published in 1779. Prof. Gino Loria, writing in the *Atti dei Lincei*, x. 7, now gives an investigation of the criteria of divisibility by any integer in a comparatively simple form.

A SERIES of experiments on the period of a rod vibrating in a liquid is described by Mary J. Northway and A. Stanley Mackenzie in the *Physical Review* for September. The lowering of pitch, which is, of course, due mainly to the inertia of the fluid particles, is found in these experiments to conform to the following general approximate results:—The interval of lowering for a rod of given cross section is independent of the length. It is also approximately the same for brass and steel and is probably independent of the material within the range of substances ordinarily used. The interval of lowering for a rod of given width is approximately inversely proportional to the thickness, while for a rod of given thickness it is approximately directly proportional to the width. From the experiments, which were made both in water and cotton-seed oil, the authors calculate for the rods of different section the coefficient by which the mass of the displaced liquid must be multiplied in order, when added to the mass of the solid, to represent the effect of fluid inertia, *i.e.* the well-known coefficient which is proved in hydrodynamics to be unity for a cylinder and one half for a sphere moving in perfect fluid. The rods used in these experiments appear to have had a rectangular cross section. It would be interesting to inquire whether they had sharp edges, and under what conditions such edges tend to increase the damping of the oscillations.

THOSE engaged in or about to commence the production of coloured pictures by means of a camera will find much to interest them in the catalogue of apparatus, material and appliances which has just been received from Messrs. Sanger Shepherd and Co. In the process under consideration, many of the difficulties that were conspicuous in the Ives process have been eliminated, so that the procedure is in the reach of every photographer and the equipment required reduced to a minimum. By using the very carefully adjusted colour filters and printing-colours of exactly the correct absorption, which are here placed within the reach of anyone, and by providing oneself with the repeating back for the three separate negatives, a perfectly efficient outfit is secured. To make the coloured pictures, full instructions are added in a special pamphlet. The ordinary lantern may be used for throwing the pictures on the screen, and brilliant discs up to 12 feet diameter can be shown with the ordinary oxyhydrogen limelight; and with the electric arc discs up to 20 or 30 feet. A further pamphlet of Messrs. Cadett and Neall, Ltd., contains a concise account of the object of orthochromatic photography and the principles underlying its use.

WE have received reprints of an important paper by Mr. Thomas H. Holland on the Sivamalai series of elæolite-syenites and corundum-syenites in the Coimbatore district, Madras Presidency (*Mem.* Geol. Surv. India, vol. xxx. part iii., 1901). The elæolite-syenites are accompanied by augite-syenites containing olivine and other minerals. These rocks are also associated with others made up principally of felspar (albite and orthoclase), containing large quantities of well-crystallised, generally tabular, corundum, which is extracted by the villagers near the junction of the felspar-rock with the elæolite-syenite. It is remarked that the association of rocks is remarkably similar to that described in eastern Ontario, and also in the Urals.

THE methods of improving ocean bars are discussed by Mr. Lewis M. Haupt in the *Proceedings* of the American Philosophical Society for July in connection with the proposed improvements at Brunswick Outer Bar, Georgia. There are at least five methods available for creating navigable channels, namely, by the use of dynamite, by a single jetty, by a single curved breakwater, by twin jetties, and by dredging. Of the several methods proposed for bar removal by the use of single or double jetties or by the reaction breakwater, the latter, so far as it has been tested, fulfils better than any other the conflicting requirements of harbour entrances, costs less than half as much, and is far cheaper to maintain.

M. CHARLES RABOT publishes, in the August and September numbers of *La Geographie*, a full summary of the chief contributions to the literature of limnology which have appeared during the past year. The work done in each country is dealt with under a separate heading, and the paper includes a review of Prof. Forel's "Handbuch der Seenkunde."

THE *National Geographic Magazine* for September contains an article on "German Geographers and German Geography," by Dr. Martha Krug Genthe. A summary is given of the work associated with the names of Behaim, Kant, Humboldt, Ritter, Berghaus, Richthofen and Ratzel, and some account of the present position of geography in German education. The magazine also contains a note by Mr. R. Muldrow on Mount McKinley, in Alaska, the highest mountain in North America. A series of theodolite measurements from points on a stadia line run up the Shushitna River gives the position of the mountain in lat. 63° 5′ N., long. 151° 0′ W., and its height at 20,464 feet.

THE September number of *Naturen*, the excellent popular journal issued by the Bergen Museum, contains an article on the dipper, and a second on the European bison.

IN the *Memorias y Revista* "Antonio Alzate," Señor L. Herrera publishes the second instalment of his remarkable scheme for an abbreviated biological and mineralogical nomenclature.

IN the October issue of the *Zoologist* Mr. L. J. Bevir discusses Dante as a naturalist, while the Rev. H. A. Macpherson contributes some interesting particulars with regard to the work of early ornithologists.

The Zambesi Mission Record usually contains one or more articles dealing with science in a popular manner. The issue for the current month has a very readable illustrated communication entitled "A Chat about Snakes," from the pen of the Rev. J. O'Neil.

ACCORDING to the October issue of *The Naturalist*, the members of the Yorkshire Naturalists' Club enjoyed a most successful outing at Wykeham, near Scarborough, on June 22. Perhaps the feature of the day was the number of fritillary butterflies seen on the wing.

MESSRS. W. AND G. S. WEST have completed their alga-flora of Yorkshire in the *Transactions* of the Yorkshire Naturalists' Union. The enumeration makes up 1044 species.

AMONG the lectures to be delivered at the Royal Victoria Hall, Waterloo Road, during the month of November we notice the following :—November 5, "Lightning and other forms of the Electric Discharge," by Prof. A. W. Porter ; November 26, "Student Life in Germany," by Dr. A. W. Crossley.

THE syllabus of the Hampstead Scientific Society for 1901–2 has reached us, and gives promise of a full and interesting session. The opening meeting will be held on November 1, when the president, Sir Richard Temple, will deliver an address.

THOSE of our readers who are on the look-out for cheap scientific books should see the new catalogue of remainders, &c., which has just been issued by Mr. H. J. Glaisher, of Wigmore Street, W. In it are to be found the titles of very many such works at greatly reduced prices.

THE following American botanical publications have been received :—"The Willows of Alaska," by Frederick V. Colville, from the *Proceedings* of the Washington Academy of Sciences ; and the "Violet-rusts of North America," by J. C. Arthur and E. W. D. Holday, reprinted from the *Minnesota Botanical Studies*. They consist of three species, *Aecidium pedatum*, *Puccinia Violae*, and *P. effusa*.

THE *Journal* of the Royal Microscopical Society for October contains a further instalment of Mr. F. W. Millett's report on the recent foraminifera of the Malay Archipelago collected by Mr. A. Durrand. The summary of current researches is noteworthy as indicating the attention now being paid to the construction of microtomes, no less than seven new instruments or improvements on old instruments being described. Abstracts are given of a number of recently published important papers on microscopic metallography, several of them illustrated by halftone plates.

TWO papers by Ciamician and Silber have appeared in recent numbers of the *Berichte*, which describe a series of interesting experiments on the action of light in promoting mutual oxidation and reduction between organic compounds. This change is specially interesting in connection with the chemical effects brought about by light in plant life. The oxidising agent is represented by a ketone, diketone or aldehyde, those of the aromatic series being the most active. They undergo reduction into alcohol or pinacone. The reducing agent is an alcohol or ordinary ether, the alcohol being converted into aldehyde or ketone. The product of oxidation of ether has not been determined. Thus quinone dissolved in ethyl alcohol, sealed up and exposed to sunlight, gives quinol and aldehyde ; quinone and isopropyl alcohol give quinol and acetone ; glycerol is oxidised to glycerose (dioxyacetone), erythritol to erythrose, &c. On the other hand, benzophenone in presence of alcohol is reduced to benzopinacone, benzaldehyde to hydrobenzoin, &c. Curiously enough, even such stable substances as the paraffins and benzene undergo oxidation with quinone, black products being obtained, which have not yet been investigated. Still more remarkable is the action of light on ortho-nitrobenzaldehyde either dry or dissolved in various solvents. It is then converted into ortho-nitrosobenzoic acid $C_6H_4(NO_2)COH = C_6H_4(NO).COOH$. In presence of methyl or ethyl alcohol, the corresponding ester is formed. Under like conditions, meta-nitrobenzaldehyde gives resinous products, and the para-compound remains for the greater part unchanged.

THE additions to the Zoological Society's Gardens during the past week include a Ruff (*Machetes pugnax*), European, presented by Mr. W. H. Dobie ; six Common Pheasants (*Phasianus colchicus*, white var.), British, presented by Sir J. Haggerston, Bart. ; a Bronze-winged Parrot (*Pionus chalcopterus*) from Colombia, a Naked-footed Owlet (*Athene noctua*), European, deposited ; four North African Jackals (*Canis anthus*), two Fennec Foxes (*Canis cerdo*) from North Africa, received in exchange.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN NOVEMBER.

Nov. 2. 2h. 55m. to 6h. 8m. Transit of Jupiter's Sat. III.
3. 9h. 33m. Minimum of Algol (β Persei).
3. 12h. 4m. to 12h. 30m. Moon occults ω Leonis (mag. 5·6).
6. 6h. 22m. Minimum of Algol (β Persei).
9. 7h. 13m. Transit (ingress) of Jupiter's Sat. III.
10. Annular eclipse of the sun, invisible at Greenwich.
14–15. Epoch of Leonid meteoric shower (radiant 150° +22°).
15. 8h. Jupiter in conjunction with moon. Jupiter 4° 44′ S.
15. 10h. Saturn in conjunction with moon. Saturn 4° 21′ S.
15. Venus. Illuminated portion of disc = 0·591, of Mars = 0·967.
17. 18h. Venus in conjunction with Jupiter. Venus 2° 45′ S.
18. 19h. Venus in conjunction with Saturn. Venus 3° 12′ S.
20. 17h. Mercury at greatest elongation west, 19° 42′.
23. 11h. 15m. Minimum of Algol (β Persei).
24. Epoch of Andromedid meteoric shower (radiant 24° + 43°).
25. 8h. 11m. to 9h. 0m. Moon occults B.A.C. 1240 (mag. 5·7).
25. 17h. 14m. to 18h. 7m. Moon occults D.M. + 18°, 624 (mag. 5·9).
26. 8h. 4m. Minimum of Algol (β Persei).
27. 10h. 41m. to 10h. 54m. Moon occults 71 Orionis (mag. 5·1).
27. 18h. Jupiter in conjunction with Saturn. Jupiter 0° 27′ S.
28. 19h. 18m. to 20h. 6m. Moon occults 68 Geminorum (mag. 5·0).
30. 9h. 54m. to 10h. 24m. Moon occults κ Cancri (mag. 5·0).

PERIOD OF MIRA (ο CETI).—In the *Astronomische Nachrichten* (Bd. 157, No. 3745), Herr P. Guthnick classifies many of the available observations of this star, and from them deduces a mean value of the period. Sets of specially bright or faint maxima and minima are grouped together, the frequent long gaps, however, making the detailed form of the light curve somewhat uncertain. The minima may be determined from the formula

$$1883 \text{ January } 12{\cdot}09 + 331\text{d}{\cdot}3359\ E.$$

An ephemeris is given showing the predicted times of maxima and minima for the next twenty years.

THE POSSIBLE IMPROVEMENT OF THE HUMAN BREED UNDER THE EXISTING CONDITIONS OF LAW AND SENTIMENT.[1]

IN fulfilling the honourable charge that has been entrusted to me of delivering the Huxley lecture, I shall endeavour to carry out what I understand to have been the wish of its founders, namely, to treat broadly some new topic belonging to a class in which Huxley himself would have felt a keen interest, rather than to expatiate on his character and the work of his noble life.

That which I have selected for to-night is one which has occupied my thoughts for many years, and to which a large part of my published inquiries have borne a direct though silent reference. Indeed, the remarks I am about to make would serve as an additional chapter to my books on "Hereditary Genius" and on "Natural Inheritance." My subject will be the possible improvement of the human race under the existing conditions of law and sentiment. It has not hitherto been approached along the ways that recent knowledge has laid open, and it occupies in consequence a less dignified position in scientific estimation than it might. It is smiled at as most desirable in itself and possibly worthy of academic discussion, but absolutely out of the question as a practical problem. My aim in this lecture is to show cause for a different opinion. Indeed I hope to induce anthropologists to regard human improvement as a subject that should be kept openly and squarely in view, not only on account of its transcendent importance, but also because it affords excellent but neglected fields for investigation. I shall show that our knowledge is already sufficient to justify the pursuit of this perhaps the grandest of all objects, but that we know less of the conditions upon which success depends than we might and ought to ascertain. The limits of our knowledge and of our ignorance will become clearer as we proceed.

Human Variety.—The natural character and faculties of human beings differ at least as widely as those of the domesticated animals, such as dogs and horses, with whom we are familiar. In disposition some are gentle and good-tempered, others surly and vicious; some are courageous, others timid; some are eager, others sluggish; some have large powers of endurance, others are quickly fatigued; some are muscular and powerful, others are weak; some are intelligent, others stupid; some have tenacious memories of places and persons, others frequently stray and are slow at recognising. The number and variety of aptitudes, especially in dogs, is truly remarkable; among the most notable being the tendency to herd sheep, to point and to retrieve. So it is with the various natural qualities that go towards the making of civic worth in man. Whether it be in character, disposition, energy, intellect, or physical power, we each receive at our birth a definite endowment, allegorised by the parable related in St. Matthew, some receiving many talents, others few; but each person being responsible for the profitable use of that which has been entrusted to him.

Distribution of Qualities in a Nation.—Experience shows that while talents are distributed in endless different degrees, the frequency of those different degrees follows certain statistical laws, of which the best known is the Normal Law of Frequency. This is the result whenever variations are due to the combined action of many small and different causes, whatever may be the causes and whatever the object in which the variations occur, just as twice 2 always makes 4, whatever the objects may be. It therefore holds true with approximate precision for variables of totally different sorts, as, for instance, stature of man, errors made by astronomers in judging minute intervals of time, bullet marks around the bull's-eye in target practice, and differences of marks gained by candidates at competitive examinations. There is no mystery about the fundamental principles of this abstract law; it rests on such simple fundamental conceptions as, that if we toss two pence in the air they will, in the long run, come down one head and one tail twice as often as both heads or both tails. I will assume then, that the talents, so to speak, that go to the formation of civic worth are distributed with rough approximation according to this familiar law. In doing so, I in no way disregard the admirable work of Prof. Karl Pearson on the distribution of qualities, for which he was adjudged the Darwin Medal of the Royal Society a few years ago. He has amply proved that we must not blindly trust the Normal Law of Frequency; in fact, that when variations are minutely studied they rarely fall into that perfect symmetry about the mean value which is one of its consequences. Nevertheless, my conscience is clear in using this law in the way I am about to. I say that *if* certain qualities vary normally, such and such will be the results; that these qualities are of a class that are found, whenever they have been tested, to vary normally to a fair degree of approximation, and consequently we may infer that our results are trustworthy indications of real facts.

A talent is a sum whose exact value few of us care to know, although we all appreciate the inner sense of the beautiful parable. I will, therefore, venture to adapt the phraseology of the allegory to my present purpose by substituting for "talent" the words "normal-talent." The value of this normal talent in respect to each and any specified quality or faculty is such that one-quarter of the people receive for their respective shares more than one normal-talent *over and above* the average of all the shares. Our normal-talent is therefore identical with what is technically known as the "probable error." Therefrom the

[1] The second Huxley Lecture of the Anthropological Institute, delivered by Francis Galton, D.C.L., D.Sc., F.R.S., on October 29, 1901.

whole of the following table starts into life, evolved from that of the "*probability integral.*" It expresses the distribution of

TABLE I.—*Normal Distribution* (*to the nearest* per *ten-thousand and to the nearest* per *hundred*).

	−4°		−3°	−2°	−1°	M	+1°	+2°	+3°	+4°	
v and below	*u*	*t*	*s*	*r*	R	S	T	U	V and above.	Total
35	180	672	1613	2500	2500	1613	672	180	35	10,000
2		7	16	25	25	16	7	2		100

any normal quality, or any group of normal qualities, among 10,000 persons in terms of the normal-talent. The M in the upper line occupies the position of Mediocrity, or that of the average of what all have received: the $+1^\circ$, $+2^\circ$, etc., and the -1°, -2°, etc., refer to normal talents. These numerals stand as graduations at the heads of the vertical lines by which the table is divided. The entries between the divisions are the numbers per 10,000 of those who receive sums between the amounts specified by those divisions. Thus, by the hypothesis, 2500 receive more than M but less than $M+1^\circ$, 1613 receive more than $M+1^\circ$ but less than $M+2^\circ$, and so on. The terminals have only an inner limit; thus 35 receive more than 4°, some, to perhaps a very large but indefinite amount. The divisions might have been carried much farther, but the numbers in the classes between them would become less and less trustworthy. The left half of the series exactly reflects the right half. As it will be useful henceforth to distinguish these classes, I have used the *capital* or large letters R, S, T, U, V, for those above mediocrity and corresponding *italic* or small letters, *r*, *s*, *t*, *u*, *v*, for those below mediocrity, *r* being the counterpart of R, *s* of S, and so on.

In the lowest line the same values are given, but more roughly, to the nearest whole percentage.

It will assist in comprehending the values of different grades of civic worth to compare them with the corresponding grades of adult male stature in our nation. I will take the figures from my "Natural Inheritance," premising that the distribution of stature in various peoples has been well investigated and shown to be closely normal. The average height of the adult males, to whom my figures refer, was nearly 5 feet 8 inches, and the value of their "normal-talent" (which is a measure of the spread of distribution) was very nearly $1\frac{3}{4}$ inches. From these data it is easily reckoned that Class U would contain men whose heights exceed 6 feet $1\frac{1}{4}$ inches. Even they are tall enough to overlook a hatless mob, while the higher classes, such as V, W and X, tower above it in an increasingly marked degree. So the civic worth (however that term may be defined) of U-class men, and still more of V-class, are notably superior to the crowd, though they are far below the heroic order. The rarity of a V-class man in each specified quality or group of qualities is as 35 in 10,000, or say, for the convenience of using round numbers, as 1 to 300. A man of the W class is ten times rarer, and of the X class rarer still; but I shall avoid giving any more exact definition of X than as a value considerably rarer than V. This gives a general but just idea of the distribution throughout a population of each and every quality taken separately so far as it is normally distributed. As already mentioned, it does the same for *any* group of normal qualities; thus, if marks for classics and for mathematics were severally normal in their distribution, the combined marks gained by each candidate in both those subjects would be distributed normally also, this being one of the many interesting properties of the law of frequency.

Comparison of the Normal Classes with those of Mr. Booth.—Let us now compare the normal classes with those into which Mr. Charles Booth has divided the population of all London, in a way that corresponds not unfairly with the ordinary conception of grades of civic worth. He reckons them from the lowest upwards, and gives the numbers in each class for East London. Afterwards he treats all London in a similar manner, except that sometimes he combines two classes into one and gives the joint result. For my present purpose, I had to couple them somewhat differently, first disentangling them as I best could. There seemed no better way of doing this than by assigning to the members of each couplet the same proportions that they had in East London. Though this was certainly not accurate, it is probably not far wrong. Mr. Booth has taken unheard-of pains in this great work of his to arrive at accurate results, but he emphatically says that his classes cannot be separated sharply from one another. On the contrary, their frontiers blend, and this justifies me in taking slight liberties with his figures. His class A consists of criminals, semi-criminals, loafers and some others, who are in number at the rate of 1 per cent. in all London—that is 100 per 10,000, or nearly three times as many as the *v* class: they therefore include the whole of *v* and spread upwards into the *u*. His class B consists of very poor persons who subsist on casual earnings, many of whom are inevitably poor from shiftlessness, idleness or drink. The numbers in this and the A class combined closely correspond with those in *t* and all below *t*.

TABLE II.—*Comparison of Mr. Booth's Classification of All London with the Normal Classes.*

Nos.	Mr. Booth's classes.	Approx	Resorted.	Approx.	Nos.	Normal classes.

1000		1000		1000	1000	

The two columns headed "Nos." give respectively the numbers per thousand in Mr. Booth's and in the normal classes.

Class C are supported by intermittent earnings; they are a hard-working people, but have a very bad character for improvidence and shiftlessness. In Class D the earnings are regular, but at the low rate of twenty-one shillings or less a week, so none of them rise above poverty, though none are very poor. D and C together correspond to the whole of *s* combined with the lower fifth of *r*. The next class, E, is the largest of any, and comprises all those with regular standard earnings of twenty-two to thirty shillings a week. This class is the recognised field for all forms of cooperation and combination; in short for trades unions. It corresponds to the upper four-fifths of *r* and the lower four-fifths of R. It is therefore essentially the mediocre class, standing as far below the highest in civic worth as it stands above the lowest class with its criminals and semi-criminals. Next above this large mass of mediocrity comes the honourable class *F*, which consists of better paid artisans and foremen. These are able to provide adequately for old age, and their sons become clerks and so forth. *G* is the lower middle class of shop-keepers, small employers, clerks and subordinate professional men, who as a rule are hard-working, energetic and sober. F and G combined correspond to the upper fifth of R and the whole of S, and are, therefore, a counterpart to D and C. All above G are put together by Mr. Booth into one class H, which corresponds to our T, U, V and above, and is the counterpart of his two lowermost classes, A and B. So far, then, as these figures go, civic worth is distributed in fair approximation to the normal law of frequency. We also see that the classes *t*, *u*, *v* and below are undesirables.

Worth of Children.—The brains of the nation lie in the higher of our classes. If such people as would be classed W or X could be distinguishable as children and procurable by money in order to be reared as Englishmen, it would be a cheap bargain for the nation to buy them at the rate of many hundred or some thousands of pounds per head. Dr. Farr, the eminent statistician, endeavoured to estimate the money worth of an average baby born to the wife of an Essex labourer and thenceforward living during the usual time and in the ordinary way of his class. Dr. Farr, with accomplished actuarial skill, capitalised the value at the child's birth of two classes of events, the one the cost of maintenance while a child and when helpless through old age, the other its earnings as boy and man. On balancing the two sides of the account the value of the baby was found to be five pounds. On a similar principle, the worth of an X-class baby would be reckoned in thousands of pounds. Some such "talented" folk fail, but most succeed, and many succeed greatly. They found great industries, establish vast undertakings, increase the wealth of multitudes and amass large fortunes for themselves. Others, whether they be rich or poor, are the guides and light of the nation, raising its tone, enlightening its difficulties and imposing its ideals. The great gain that England received through the immigration of the Huguenots would be insignificant to what she would derive from an annual addition of a few hundred children of the classes W and X. I have tried, but not yet succeeded to my satisfaction, to make an approximate estimate of the worth of a child at birth according to the class he is destined to occupy when adult. It is an eminently important subject for future investigators, for the amount of care and cost that might profitably be expended in improving the race clearly depends on its result.

Descent of Qualities in a Population.—Let us now endeavour to obtain a correct understanding of the way in which the varying qualities of each generation are derived from those of its predecessor. How many, for example, of the V class in the offspring come respectively from the V, U, T, S and other classes of parentage? The means of calculating this question for a normal population are given fully in my "Natural Inheritance." There are three main senses in which the word parentage might be used. They differ widely, so the calculations must be modified accordingly. (1) The amount of the quality or faculty in question may be known in each parent. (2) It may be known in only one parent. (3) The two parents may belong to the same class, a V-class father in the scale of male classification always marrying a V-class mother, occupying identically the same position in the scale of female classification.

I select this last case to work out as being the one with which we shall here be chiefly concerned. It has the further merit of escaping some tedious preliminary details about converting female faculties into their corresponding male equivalents, before men and women can be treated statistically on equal terms. I shall assume in what follows that we are dealing with an ideal population, in which all marriages are equally fertile, and which is statistically the same in successive generations both in numbers and in qualities, so many per cent. being always this, so many always that, and so on. Further, I shall take no notice of offspring who die before they reach the age of marriage, nor shall I regard the slight numerical inequality of the sexes, but will simply suppose that each parentage produces one couplet of grown-up filials, an adult man and an adult woman.

The result is shown to the nearest whole per thousand in the diagram up to "U and above," and in the table up to "V and

TABLE III.—*Descent of Qualities in a Population.* (*The difference between the sexes only affects the value of the Unit of the Scale of Distribution*).

Conditions.—(1) Parents to be always alike in class, (2) Statistics of population to continue unchanged, (3) Normal Law of Frequency to be applicable throughout.

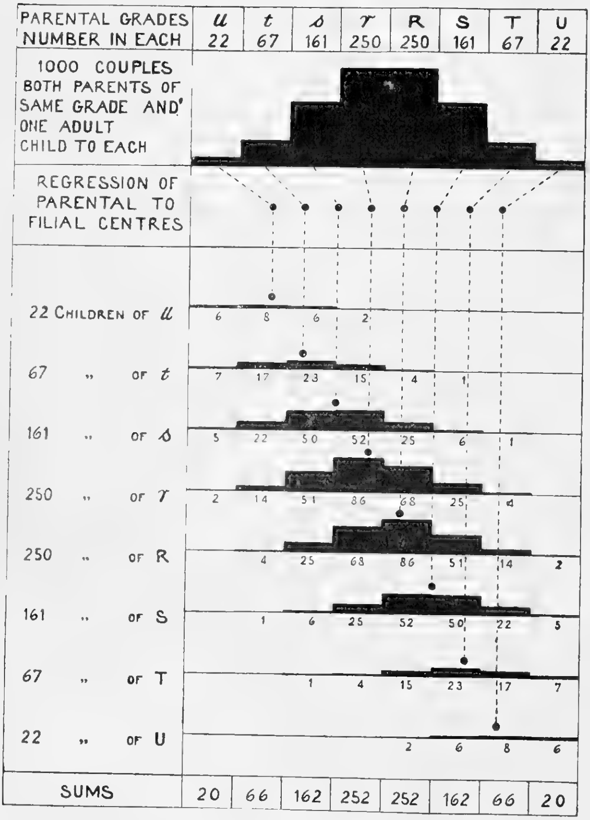
Note.—The agreement in distribution between fathers (or *mothers*) and sons (or *daughters*) is exact to the nearest whole per centage. The slight discrepancy in the ten-thousandths is mainly due to the classes being too few and too wide; theoretically they should be extremely numerous and narrow.

above," to the nearest ten-thousandth. They may be read either as applying to fathers and their sons when adult, or to mothers and their daughters when adult, or, again, to parentages and filial couplets. I will not now attempt to explain the details of the calculation to those to whom these methods are new. Those who are familiar with them will easily understand the exact process from what follows. There are three points of reference in a scheme of descent which may be respectively named "mid-parental," "genetic" and "filial" centres. In the present case of both parents being alike, the position of the mid-parental centre is identical with that of either parent separately. The position of the filial centre is that from which the children disperse. The genetic centre occupies the same position in the parental series that the filial centre does in the filial series. "Natural Inheritance" contains abundant proof, both observational and theoretical, that the genetic centre is not and cannot be identical with the parental centre, but is always more mediocre, owing to the combination of ancestral influences—which are generally mediocre—with the purely parental ones. It also shows that the regression from the parental to the genetic centre, in the case of stature at least, would amount to two-thirds under the conditions we are now supposing. The regression is indicated in the diagram by converging lines which are directed towards the same point below, but are stopped at one-third of the distance on the way to it. The contents of each parental class are supposed to be concentrated at the foot of the median axis of that class, this being the vertical line that divides its contents into equal parts. Its position is approximately, but not exactly, half-way between the divisions that bound it, and is as easily calculated for the extreme classes, which have no outer terminals, as for any of the others. These median points are respectively taken to be the positions of the parental centres of the whole of each of the classes; therefore the positions attained by the converging lines that proceed from them at the points where they are stopped, represent the genetic centres. From these the filials disperse to the right and left with a "spread" that can be shown to be three-quarters that of the parentages. Calculation easily determines the number of the filials that fall into the class in which the filial centre is situated, and of those that spread into the classes on each side. When the parental contributions from all the classes to each filial class are added together they will express the distribution of the quality among the whole of the offspring. Now it will be observed in the table that the numbers in the classes of the offspring are identical with those of the parents, when they are reckoned to the nearest whole percentage, as should be the case according to the hypothesis. Had the classes been narrower and more numerous, and if the calculations had been carried on to two more places of decimals, the correspondence would have been identical to the nearest ten-thousandth. It was unnecessary to take the trouble of doing this, as the table affords a sufficient basis for what I am about to say. Though it does not profess to be more than approximately true in detail, it is certainly trustworthy in its general form, including as it does the effects of regression, filial dispersion, and the equation that connects a parental generation with a filial one when they are statistically alike. Minor corrections will be hereafter required, and can be applied when we have a better knowledge of the material. In the meantime it will serve as a standard table of descent from each generation of a people to its successor.

STANDARD SCHEME OF DESCENT



Economy of Effort.—I shall now use the table to show the economy of concentrating our attention upon the highest classes. We will therefore trace the origin of the V class—which is the highest in the table. Of its 34 or 35 sons, 6 come from V parentages, 10 from U, 10 from T, 5 from S, 3 from R, and none from any class below R. But the numbers of the contributing parentages have also to be taken into account. When this is done, we see that the lower classes make their scores owing to their quantity and not to their quality; for while 35 V-class parents suffice to produce 6 sons of the V class, it takes 2500 R-class fathers to produce 3 of them. Consequently the richness in produce of V-class parentages is to that of the R-class in an inverse ratio, or as 143 to 1. Similarly, the richness in produce of V-class children from parentages of the classes U, T, S, respectively, is as 3, 11½ and 55, to 1. Moreover, nearly one-half of the produce of V-class parentages are V or U taken together, and nearly three-quarters of them are either V, U or T. If then we desire to increase the output of V-class offspring, by far the most profitable parents to work upon would be those of the V class, and in a threefold less degree those of the U class.

When both parents are of the V class the quality of parentages is greatly superior to those in which only one parent is a

V. In that case the regression of the genetic centre goes twice as far back towards mediocrity, and the spread of the distribution among filials becomes nine-tenths of that among the parents, instead of being only three-quarters. The effect is shown in Table IV.

TABLE IV.—*Distribution of Sons.* (1) *One parent of class* V., *the other unknown.* (2) *Both parents of class* V (*from Table II., with decimal point and an* 0).

	Distribution of Sons								Total
	t	*s*	*r*	R	S	T	U	V	
One V-parent ...	0·3	1·2	3·5	7·9	9·6	7·5	3·6	1·3	34·3
Two V-parents				3·0	5·0	10·0	10·0	6·0	34·0

Position of the filial centre of (1) = 1·44, of (2) = 2·89. When both parents are T it = 1·58.

There is a difference of fully two divisions in the position of the genetic centre, that of the single V parentage being only a trifle nearer mediocrity than that of the double T. Hence it would be bad economy to spend much effort in furthering marriages with a high class on only one side.

Marriage of Like to Like.—In each class of society there is a strong tendency to intermarriage, which produces a marked effect in the richness of brain power of the more cultured families. It produces a still more marked effect of another kind at the lowest step of the social scale, as will be painfully evident from the following extracts from the work of Mr. C. Booth (i. 38), which refer to his Class A, who form, as has been said, the lowermost third of our "*v* and below." "Their life is the life of savages, with vicissitudes of extreme hardship and occasional excess. From them come the battered figures who slouch through the streets and play the beggar or the bully. They render no useful service, they create no wealth; more often they destroy it. They degrade whatever they touch, and as individuals are perhaps incapable of improvement . . . but I do not mean to say that there are not individuals of every sort to be found in the mass. Those who are able to wash the mud may find some gems in it. There are at any rate many very piteous cases. Whatever doubt there may be as to the exact numbers of this class, it is certain that they bear a very small proportion to the rest of the population, or even to Class B, with which they are mixed up and from which it is at times difficult to separate them. . . . They are barbarians, but they are a handful. . . ." He says further, "It is much to be desired and to be hoped that this class may become less hereditary in its character; there appears to be no doubt that it is now hereditary to a very considerable extent."

Many who are familiar with the habits of these people do not hesitate to say that it would be an economy and a great benefit to the country if all habitual criminals were resolutely segregated under merciful surveillance and peremptorily denied opportunities for producing offspring. It would abolish a source of suffering and misery to a future generation, and would cause no unwarrantable hardship in this.

Diplomas.—It will be remembered that Mr. Booth's classification did not help us beyond classes higher than S in civic worth. If a strong and widely felt desire should arise, to discover young men whose position was of the V, W or X order, there would not be much difficulty in doing so. Let us imagine, for a moment, what might be done in any great University, where the students are in continual competition in studies, in athletics, or in public meetings, and where their characters are publicly known to associates and to tutors. Before attempting to make a selection, acceptable definitions of civic worth would have to be made in alternative terms, for there are many forms of civic worth. The number of men of the V, W or X classes whom the University was qualified to contribute annually must also be ascertained. As was said, the proportion in the general population of the V class to the remainder is as 1 to 300, and that of the W class as 1 in 3000. But students are a somewhat selected body because the cleverest youths, in a scholastic sense, usually find their way to Universities. A considerably high level, both intellectually and physically, would be required as a qualification for candidature. The limited number who had not been automatically weeded away by this condition might be submitted in some appropriate way to the independent votes of fellow-students on the one hand, and of tutors on the other, whose ideals of character and merit necessarily differ. This ordeal would reduce the possible winners to a very small number, out of which an independent committee might be trusted to make the ultimate selection. They would be guided by personal interviews. They would take into consideration all favourable points in the family histories of the candidates, giving appropriate hereditary weight to each. Probably they would agree to pass over unfavourable points, unless they were notorious and flagrant, owing to the great difficulty of ascertaining the real truth about them. Ample experience in making selections has been acquired even by scientific societies, most of which work well, including perhaps the award of their medals, which the fortunate recipients at least are tempted to consider judicious. The opportunities for selecting women in this way are unfortunately fewer, owing to the smaller number of female students between whom comparisons might be made on equal terms. In the selection of women, when nothing is known of their athletic proficiency, it would be especially necessary to pass a high and careful medical examination; and as their personal qualities do not usually admit of being tested so thoroughly as those of men, it would be necessary to lay all the more stress on hereditary family qualities, including those of fertility and prepotency.

Correlation between Promise in Youth and subsequent Performance.—No serious difficulty seems to stand in the way of classifying and giving satisfactory diplomas to youths of either sex, supposing there were a strong demand for it. But some real difficulty does lie in the question—Would such a classification be a trustworthy forecast of qualities in later life? The scheme of descent of qualities may hold good between the parents and the offspring at similar ages, but that is not the information we really want. It is the descent of qualities from men to men, not from youths to youths. The accidents that make or mar a career do not enter into the scope of this difficulty. It resides entirely in the fact that the development does not cease at the time of youth, especially in the higher natures, but that faculties and capabilities which were then latent subsequently unfold and become prominent. Putting aside the effects of serious illness, I do not suppose there is any risk of retrogression in capacity before old age comes on. The mental powers that a youth possesses continue with him as a man; but other faculties and new dispositions may arise and alter the balance of his character. He may cease to be efficient in the way of which he gave promise, and he may perhaps become efficient in unexpected directions.

The correlation between youthful promise and performance in mature life has never been properly investigated. Its measurement presents no greater difficulty, so far as I can foresee, than in other problems which have been successfully attacked. It is one of those alluded to in the beginning of this lecture as bearing on race-improvement, and being on its own merits suitable for anthropological inquiry. Let me add that I think its neglect by the vast army of highly educated persons who are connected with the present huge system of competitive examinations to be gross and unpardonable. Neither schoolmasters, tutors, officials of the Universities, nor of the State department of education, have ever to my knowledge taken any serious step to solve this important problem, though the value of the present elaborate system of examinations cannot be rightly estimated until it is solved. When the value of the correlation between youthful promise and adult performance shall have been determined, the figures given in the table of descent will have to be reconsidered.

Augmentation of Favoured Stock.—The possibility of improving the race of a nation depends on the power of increasing the productivity of the best stock. This is far more important than that of repressing the productivity of the worst. They both raise the average, the latter by reducing the undesirables, the former by increasing those who will become the lights of the nation. It is therefore all important to prove that favour to selected individuals might so increase their productivity as to warrant the expenditure in money and care that would be necessitated. An enthusiasm to improve the race would probably express itself by granting diplomas to a select class of young men and women, by encouraging their intermarriages, by hastening the time of marriage of women of that high class, and by provision for rearing children healthily. The means that might be employed to compass these ends are dowries, especially for those to whom moderate sums are important, assured help in emergencies during the early years of married life, healthy homes, the pressure of public opinion, honours, and above all the introduction of motives of religious or quasi-religious character. Indeed, an enthusiasm to improve the race is so noble in its aim that it might well give rise to the sense of a religious obligation. In other lands there are abundant instances in which religious motives make early marriages a matter of custom, and continued celibacy to be regarded as a disgrace, if not a crime. The customs of the Hindoos, also of the Jews, especially in ancient times, bear this out. In all costly civilisations there is a tendency to shrink from marriage on prudential grounds. It would, however, be possible so to alter the conditions of life that the most prudent course for an X class person should lie exactly opposite to its present direction, for he or she might find that there were advantages and not disadvantages in early marriage, and that the most prudent course was to follow their natural instincts.

We have now to consider the probable gain in the number and worth of adult offspring to these favoured couples. First as regards the effect of reducing the age at marriage. There is unquestionably a tendency among cultured women to delay or even to abstain from marriage; they dislike the sacrifice of freedom and leisure, of opportunities for study and of cultured companionship. This has to be reckoned with. I heard of the reply of a lady official of a College for Women to a visitor who inquired as to the after life of the students. She answered that one-third profited by it, another third gained little good, and a third were failures. "But what becomes of the failures?" "Oh, hey marry."

There appears to be a considerable difference between the earliest age at which it is physiologically desirable that a woman should marry and that at which the ablest, or at least the most cultured, women usually do. Acceleration in the time of marriage, often amounting to 7 years, as from 28 or 29 to 21 or 22, under influences such as those mentioned above, is by no means improbable. What would be its effect on productivity? It might be expected to act in two ways:—

(1) By shortening each generation by an amount roughly proportionate to the diminution in age at which marriage occurs. Suppose the span of each generation to be shortened by one-sixth, so that six take the place of five, and that the productivity of each marriage is unaltered, it follows that one-sixth more children will be brought into the world during the same time, which is, roughly, equivalent to increasing the productivity of an unshortened generation by that amount.

(2) By saving from certain barrenness the earlier part of the child-bearing period of the woman. Authorities differ so much as to the direct gain of fertility due to early marriage that it is dangerous to express an opinion. The large and thriving families that I have known were the offspring of mothers who married very young.

The next influence to be considered is that of healthy homes. These and a simple life certainly conduce to fertility. They also act indirectly by preserving lives that would otherwise fail to reach adult age. It is not necessarily the weakest who perish in this way, for instance, zymotic disease falls indiscriminately on the weak and the strong.

Again, the children would be healthier and therefore more likely in their turn to become parents of a healthy stock. The great danger to high civilisations, and remarkably so to our own, is the exhaustive drain upon the rural districts to supply large towns. Those who come up to the towns may produce large families, but there is much reason to believe that these dwindle away in subsequent generations. In short, the towns sterilise rural vigour.

As one of the reasons for choosing the selected class would be that of hereditary fertility, it follows that the selected class would respond more than other classes to the above influences.

I do not attempt to appraise the strength of the combined six influences just described. If each added one-sixth to the produce the number of offspring would be doubled. This does not seem impossible considering the large families of colonists, and of those in many rural districts; but it is a high estimate. Perhaps the fairest approximation may be that these influences would cause the X women to bring into the world an average of one adult son and one adult daughter *in addition* to what they would otherwise have produced. The table of descent applies to one son or to one daughter per couple; it may now be read as specifying the net gain and showing its distribution. Should this estimate be thought too high, the results may be diminished accordingly.

It is no absurd idea that outside influences should hasten the age of marrying and make it customary for the best to marry the best. A superficial objection is sure to be urged that the fancies of young people are so incalculable and so irresistible that they cannot be guided. No doubt they are so in some exceptional cases. I lately heard from a lady who belonged to a county family of position that a great aunt of hers had scandalised her own domestic circle two generations ago by falling in love with the undertaker at her father's funeral and insisting on marrying him. Strange vagaries occur, but considerations of social position and of fortune, with frequent opportunities of intercourse, tell much more in the long run than sudden fancies that want roots. In a community deeply impressed with the desire of encouraging marriages between persons of equally high ability, the social pressure directed to produce the desired end would be so great as to ensure a notable amount of success.

Profit and Loss.—The problem to be solved now assumes a clear shape. A child of the X class (whatever X signifies) would have been worth so and so at its birth, and one of each of the other grades respectively would have been worth so and so; 100 X parentages can be made to produce a net gain of 100 adult sons and 100 adult daughters who will be distributed among the classes according to the standard table of descent. The total value of the prospective produce of the 100 parentages can then be estimated by an actuary, and consequently the sum that it is legitimate to spend in favouring an X parentage. The clear and distinct statement of a problem is often more than half way towards its solution. There seems no reason why this one should not be solved between limiting values that are not too wide apar to be useful.

Existing Activities.—Leaving aside profitable expenditure from a purely money point of view, the existence should be borne in mind of immense voluntary activities that have nobler aims. The annual voluntary contributions in the British Isles to public charities alone amount, on the lowest computation, to fourteen million pounds, a sum which Sir H. Burdett asserts on good grounds is by no means the maximum obtainable. ("Hospitals and Charities," 1898, p. 85.)

There are other activities long since existing which might well be extended. I will not dwell, as I am tempted to do, on the endowments of scholarships and the like, which aim at finding and educating the fittest youths for the work of the nation; but I will refer to that wholesome practice during all ages of wealthy persons interesting themselves in and befriending poor but promising lads. The number of men who have owed their start in a successful life to help of this kind must have struck every reader of biographies. This relationship of befriender and befriended is hardly to be expressed in English by a simple word that does not connote more than is intended. The word "patron" is odious. Recollecting Dr. Johnson's abhorrence of the patrons of his day, I turned to an early edition of his dictionary in hope of deriving some amusement as well as instruction from his definition of the word, and I was not disappointed. He defines "patron" as "a wretch who supports with insolence and is repaid with flattery." That is totally opposed to what I would advocate, namely a kindly and honourable relation between a wealthy man who has made his position in the world and a youth who is avowedly his equal in natural gifts, but who has yet to make it. It is one in which each party may well take pride, and I feel sure that if its value were more widely understood it would become commoner than it is.

Many degrees may be imagined that lie between mere befriendment and actual adoption, and which would be more or less effective in freeing capable youths from the hindrances of narrow circumstances; in enabling girls to marry early and suitably, and in securing favour to their subsequent offspring. Something in this direction is commonly but half unconscioully done by many great landowners whose employments for man and wife, together with good cottages, are given to exceptionally deserving couples. The advantage of being connected with a great and liberally managed estate being widely appreciated, there are usually more applicants than vacancies, so selection can be exercised. The consequence is that the class of men found upon these properties is markedly superior to those in similar positions elsewhere. It might well become a point of honour, and as much an avowed object, for noble families to gather fine specimens of humanity around them, as it is to procure and maintain fine breeds of cattle and so forth, which are costly, but repay in satisfaction.

There is yet another existing form of princely benevolence which might be so extended as to exercise a large effect on race improvement. I mean the provision to exceptionally promising young couples of healthy and convenient houses at low rentals. A continually renewed settlement of this kind can be easily imagined, free from the taint of patronage, and analogous to colleges with their self-elected fellowships and rooms for residence, that should become an exceedingly desirable residence for a specified time. It would be so in the same way that a good club by its own social advantages attracts desirable candidates. The tone of the place would be higher than elsewhere, on account of the high quality of the inmates, and it would be distinguished by an air of energy, intelligence, health and self-respect and by mutual helpfulness.

Prospects.—It is pleasant to contrive Utopias, and I have indulged in many, of which a great society is one, publishing intelligence and memoirs, holding yearly elections, administering large funds, establishing personal relations like a missionary society with its missionaries, keeping elaborate registers and discussing them statistically with honest precision. But the first and pressing point is to thoroughly justify any crusade at all in favour of race improvement. More is wanted in the way of unbiased scientific inquiry along the many roads I have hurried over, to make every stepping-stone safe and secure, and to make it certain that the game is really worth the candle. All I dare hope to effect by this lecture is to prove that in seeking for the improvement of the race we aim at what is apparently possible to accomplish, and that we are justified in following every path in a resolute and hopeful spirit that seems to lead towards that end. The magnitude of the inquiry is enormous, but its object is one of the highest man can accomplish. The faculties of future generations will necessarily be distributed according to laws of heredity, whose statistical effects are no longer vague, for they are measured and expressed in formulæ. We cannot doubt the existence of a great power ready to hand and capable of being directed with vast benefit as soon as we shall have learnt to understand and to apply it. To no nation is a high human breed more necessary than to our own, for we plant our stock all over the world and lay the foundation of the dispositions and capacities of future millions of the human race.

OCEAN CIRCULATION.[1]

THE investigation carried on by Mr. H. N. Dickson into the distribution of temperature and salinity in the surface water of the North Atlantic is one of great importance. It promises, if continued, to be of considerable value, not only to those who are especially interested in studying the circulation of the surface water of the Ocean, but also to meteorologists generally and particularly to those who see, in a comparison of the varying yearly temperatures of the North Atlantic with that of a mean for the season, the key to a clearer knowledge of the causes which combine to influence the climate of western Europe, and especially of our Islands, and who look hopefully in that direction for information whereby future modifications in the conditions of climate may be foretold for periods some time in advance.

The treatise before us, setting forth the author's method of conducting the research and the results at which he arrived, was contributed to the Royal Society in March, 1900.

In introducing his subject the author says: "The history of our knowledge of the currents of the North Atlantic Ocean up to the year 1870 has been written once for all by Petermann," whom he quotes at some length, remarking "that the conclusions, then arrived at, were not modified by the observations of the next twenty years."

During the years 1896 and 1897 materials were collected for preparing the charts of temperature and salinity, the parallel of 40° N. being selected as the southern boundary of the area for investigation. The observations of temperature were furnished by the Meteorological Office, the Danish Meteorological Department, the United States Hydrographical Department, and the Bureau Central Météorologique de France, and by Prof. Pettersson. The samples of water for the determination of salinity were obtained from the captains of vessels keeping logs for the Meteorological Office and for the Danish Hydrographical Department, specially made bottles being supplied to them for the purpose, and no care being spared in guarding against impurity or the introduction of any matter that could give rise to error in the analytical determinations.

The accuracy of the method adopted in estimating the salinity of the samples was subjected to severe scrutiny. The author states the results of his observations, demonstrating the distribution of temperature and salinity for each month during the year 1896 as shown in the charts prepared by him, in which the isotherms and isohalines are supplemented by a scale of colouring denoting areas having the same range of temperature and the same range of salinity. He calls attention to the general agreement between the distribution of salinity as shown on the one set of charts and that of temperature as shown on the other set when apparent, and notes departures and irregularities when they occur. He then deals in the same manner with the observations of 1897 and compares results.

Taking the means of each month respectively for the two years, the distribution of temperature, as shown on these charts, corresponds fairly well with the distribution of sea-surface temperature given on the quarterly sea-temperature charts on the North Atlantic, issued by the Meteorological Office in 1884.

For the purpose of defining the limits of ocean currents and of arriving at some estimate as to its relative velocity in different localities, the information to be gained by the thermometer is invaluable, for over areas little frequented by shipping where current observations are necessarily sparse, a comparatively insignificant number of sea-surface observations will suffice to indicate the existence or failure of an ocean stream; and if to these detective signs be added observations of salinity, the evidence acquired becomes still more complete.

The effects of the cold water from the north in deflecting the warm stream from the westward are clearly shown on these charts, which, when seasonal variation in temperature has been made allowance for, appear in good agreement (speaking generally) with the monthly current charts of the North Atlantic, published by the Admiralty, as regards the area over which the warm water of the Gulf Stream is distributed each month, and the northern and western limits to which it reaches. The indications of the existence of Gulf Stream water, stated roughly, may be traced on the Admiralty Chart to the following limits in the given months:—

January.—The stream does not reach to the eastward of 20° W., and a south-easterly set is apparent off Ireland.

February.—In 55° N. it reaches 15° W.; a south-easterly set is found to the westward of Ireland, and a south-westerly to the south-westward of the Fastnet Rock.

March.—It has advanced to the coast of Ireland.

April.—In 55° N. its limit has receded to 20° W., and the Iceland south-going current begins to show itself north of 55° N.

May.—The Gulf Stream and Davies Strait cold current commingle in 47° N. 27° W., the Iceland current sets S. and S.W. to 48° N. 30° W.

June.—Gulf Stream to 15° W. in 52° N. Iceland and Denmark Strait cold currents to Irish coast.

July.—To the S. of 50° N. it joins the Iceland and Denmark Strait current in about 48° N. off the Bay of Biscay.

August.—It extends to the north of Ireland but is modified in about 20° W. by a south-going set.

September.—It extends to the north of Scotland.

October.—It is found in 10° W. in 59° N.

November.—The data are insufficient, but the Stream is traceable to 19° W. in 59° N.

December.—It is difficult to trace the Stream eastward of 40° N. in 45° W. A south-going cold current is shown to the north-westward and westward of Ireland; there is a persistent southerly (S.E. to S.W.) movement of water in the eastern half of the Atlantic.

Mr. Dickson's charts show the existence of Gulf Stream water to the northward and westward of the limits given above for several months, notably on the January chart, and the explanation doubtless is that the value of the current being small, it has been inappreciable in navigation.

There exists, during the greater part of the year, a movement of water eastward, which divides, at a varying distance to the westward of the English Channel. One arm branches towards the Bay of Biscay, the other northward (Rennell's Current). The latter is well known to the captains of the large

[1] *Phil. Trans.* of the Royal Society:—"The Circulation of the Surface Waters of the North Atlantic Ocean." By H. N. Dickson.

Transatlantic liners, who are accustomed to make allowance for it when shaping their course to sight the Fastnet. This current is well shown on the author's temperature charts for several months.

In dealing with the question of causation, the author summarises as follows: "The general circulation of the North Atlantic is therefore the result of a large number of factors, each of which is subject to wide variation. From a consideration of the mean results in its relation to the mean atmospheric circulation, it appears that the oceanic circulation is directly controlled by the winds, the form, position and intensity of the whole Atlantic anticyclone and of the cyclonic area to the north of it being taken into account. The movements of water set up directly by these systems are modified by, firstly and chiefly, the configuration of the land, and, secondly, by the effects of melting ice." And again: "The key to the position seems to be the Atlantic anticyclone which controls the low-pressure areas, both directly and indirectly, by its far-reaching effect on the oceanic circulation; and it seems scarcely likely that the causes modifying this system are confined to the Atlantic, even if they are to be found at the surface at all."

It would be regrettable if this work, so ably and successfully inaugurated, should be dropped.

Mr. Dickson mentions that it can be efficiently carried on for the sum of 300*l.* annually, and we are of opinion that the cost might be even less, for on board of almost all large liners the temperature of the sea surface is recorded at intervals of four hours with regularity, and on many, observations for specific gravity also; the rough method by which the latter is obtained is, we admit, unsatisfactory, as the hydrometer is difficult to read when subject to the least movement, but these records are better than none. In the interests of navigation alone this investigation should be continued.

It is noteworthy that, at the present time, there are many navigators who, in some measure, utilise observations of sea-surface temperature, and the time is not, we hope, far distant when the sea-surface thermometer and hydrometer may be recognised generally, as aids in determining to some extent changes in the direction and strength of ocean currents, and as affording the seaman an additional safeguard against miscalculation when approaching land in thick weather.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Natural science scholarships are announced for competition at Balliol, Christchurch and Trinity on December 3, at Magdalen on December 10, at Jesus on January 14.

Dr. J. S. Haldane, lecturer in physiology, has been elected to a fellowship at New College.

Dr. G. C. Bourne has been re-appointed lecturer in comparative anatomy for a period of three years.

Mr. O. J. R. Howarth, of Christ Church, has been elected to the geographical scholarship.

The celebration of the tercentenary of Bodley's Library will take place in October, 1902, and a delegacy of twelve will shortly be appointed to undertake the necessary arrangements.

The 227th meeting of the Oxford University Junior Scientific Club was held (Wednesday, October 23) at the Museum. The principal business of the evening was a paper by H. S. Souttar, of Queen's College, entitled "The Atom, an Electromagnetic Theory of Matter." The principal officers of the Club for this term are:—president, A. C. le Rossignol, Exeter; treasurer, E. L. Kennaway, New College; chemical secretary, E. Walls, Corpus; biological secretary, E. Burstal, Trinity; Boyle Lecture treasurer, S. A. Ionides, Balliol; editor, H. D. Davis, Balliol; members of committee, J. G. Priestley, Christ Church; Rev. G. D. Allen, non-collegiate.

CAMBRIDGE:—Mr. H. Lamb, Trinity, Mr. J. Larmor, St. John's, Mr. H. W. Richmond, King's, and Mr. E. T. Whittaker, Trinity, have been appointed examiners for the Mathematical Tripos, part 2, to be held in 1902.

Mr. W. T. N. Spivey, of Trinity College, died on October 22 from septic pneumonia following a lamentable accident which happened to him in the University Chemical Laboratory a fortnight before. Mr. Spivey was engaged in research work and was shaking two volatile and explosive liquids in a flask when an explosion occurred and he was seriously cut and burned. The sad death of this promising young chemist is much regretted.

DR. R. THAXTER has been appointed professor of cryptogamic botany at Harvard University.

AT a meeting of the Royal University of Ireland held on Friday last, the degree of D.Sc. was conferred upon Prof. W. N. Hartley, F.R.S.

A NEW Hall of Natural History is to be erected in connection with Syracuse University at the expense of an anonymous donor.

MR. F. E. REES, lecturer in physics at the Storey Institute, Lancaster, has been appointed to the lectureship and demonstratorship of physics at the University College of North Wales, Bangor.

Science states that Milliken University, Decatur, Ill., will be opened next year with an endowment of more than a million dollars, half of which sum has been given by Mr. James Milliken. Prof. S. R. Taylor, late of the Kansas State Normal School, has been appointed the president.

ADDITIONAL examiners in mathematics, chemistry, zoology, materia medica and therapeutics, medicine and clinical medicine, surgery and clinical surgery will shortly be appointed by the University of Glasgow. Applications for the appointments must be lodged on or before December 3 next.

A CIRCULAR just issued by the Board of Education describes the principles which are being followed with regard to making grants to schools and classes conducted by School Boards under the provisions of the new Education Act. When the local Authority has given a general sanction to the work of an existing school, the school is eligible for grants upon subjects taught in the twelve months preceding the passing of the Act. Extensions of the curriculum, or of the work of a school by including pupils of an age or sex not previously admitted, will not be recognised unless the specific sanction of the Local Authority has been furnished to the Board of Education.

ACCORDING to *Science*, the attendance at Cornell University, including 850 new students, is about 250 in excess of that of last year. Inclusive of the medical school in New York and the summer school at Ithaca, the total registration for the year is between 3250 and 3500. The registration on the campus, of students in regular courses, promises to be about 2750. Sibley College has a total attendance of new students, in all classes and courses, of above 350, almost equal to the total of upper classmen returning to the college, making the probable total registration for 1901–2 about 750 in all grades. The College of Civil Engineering has inceased fifty per cent., and the other colleges and departments report large additions.

THE Hon. T. Jefferson Coolidge, of Boston, has given more than 50,000 dollars to the Jefferson Physical Laboratory of Harvard University to further physical research. In the terms of the gift he states that:—"The income of this fund shall be used primarily for laboratory expenses of original investigations by members of the laboratory staff. But the Director, at his discretion, may award therefrom an honorarium, of not more than five hundred dollars per annum, for the private use of any person who—although receiving no salary from the University—may wish to carry on original investigations under his directions at the Jefferson Laboratory. The results of such investigations shall appertain to the Laboratory, and the name of the Laboratory shall accompany the investigation; but no publication shall be made without the approval of the Director. The balance of this income is to be used only for meeting the legitimate expenditures of original investigations whether by professors or students."

IN introducing Mr. James Stuart, the Lord Rector of St. Andrews University, to the gathering held at Dundee on Friday, October 25, Lord Balfour of Burleigh, the newly-elected Chancellor of the University, remarked that it was said that trade was being taken away from the country, that German chemistry had deprived Britain of the indigo trade, that we had to go to other countries for our goods, and that, generally speaking, trade in this country was in a bad way. The British manufacturer depended upon old methods, while the German employed newer. It was their business to help the manufacturers of this country to put an end to this. What was wanted in Dundee was a greater subdivision of subjects. They wanted a chair of geology and much more subdivision in the different branches of chemistry, and, first and foremost, a chair of the German language and literature. More teaching power was required and more space in which that power might exercise itself.

THE installation of Lord Balfour of Burleigh as Chancellor of the University of St. Andrews, in succession to the late Duke of Argyll, was made the occasion of a series of brilliant functions in the ancient city last week. The address delivered by Lord Balfour after his installation dealt with several important aspects of higher education, and his statement of the relationship between national progress and scientific research should be of value in showing that the work done in a progressive University is technical training of the highest kind. Referring to University studies, Lord Balfour remarked, "Besides the broad general treatment of any scientific course, the University should be enabled, as a sequel to that course, to specialise in the more advanced stages of scientific training and to encourage original research on particular lines. For this purpose the University must have full equipment and must be furnished with teachers of special attainments, who will direct and guide that original research. The students will pursue the subject as a University study, and with the view of enlarging and advancing the knowledge of their special subject. In this way only can a real advance in scientific knowledge be made; and from the students who pursue these courses—generally, I would say, post-graduate courses—we must look for the enlargement of scientific knowledge, and amongst them or as the products of their efforts we may find pioneers in the application of truly scientific method to our manufactures. A modern University must deal with the principles which lie at the root of our commercial relations, and upon which the development of manufactures must rest, just as much as it does with the principles of philology and mental philosophy. Our commercial, no less than our educational position, must be supported by a thorough training, by careful attention to principles and by imparting to young men who are to pursue commercial pursuits the power of grasping the wider aspects of the questions with which they will have to deal, and by taking care that while they obtain a training fitted to be of practical value to them in their after life, that training shall be such as will really awaken their intelligence and enable them to cultivate the inestimable qualities of judgment, of foresight and of enterprise." Upon this subject scientific and practical men are in agreement, and the demand will be met, as Lord Balfour remarked, not by curtailing the work of the Universities, or by lowering in any way their standard of scholarship or of pure science, but by enlarging their borders and extending their influence.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, October 25.—Prof. S. P. Thompson, president, in the chair.—A paper on the variation with temperature of the thermoelectromotive force and of the electric resistance of nickel, iron and copper between the temperatures of − 200° and + 1050° was read by Mr. E. P. Harrison. In this paper the changes with temperature of the thermoelectromotive force and the resistance of nickel and iron are traced over a wide range and the singularities present in the curves representing these changes are investigated. In all experiments the same specimens of metal were used. Previous work on this subject has been performed by Tait, Fleming and Dewar, Holborn and Day, and Stansfield. In the author's experiments on E.M.F. an ordinary potentiometer method was used, the potential difference due to the thermocouple being balanced against a portion of that due to two accumulators. Before each reading a standard cadmium cell was balanced on a definite resistance in the accumulator circuit. Readings of E.M.F. of copper-nickel couples were accurate to 1·8 microvolts, while those of copper-iron couples were accurate to less than one microvolt at moderate temperatures. The heating arrangement was designed to give a uniform temperature which was measured by a platinum thermometer and recorded automatically by Callendar's recorder. The cold junctions were placed in a large test-tube full of water, the test-tube being placed in a larger vessel also containing water. The temperature of the cold junctions varied with that of the room, and all observations were reduced to cold junction 0° C. Finally, in each case, observations were taken by placing the junctions in liquid air with the platinum thermometer beside them. To prevent oxidation of the metals forming the junctions at temperatures above 500° it was necessary to exhaust the porcelain tubes which contained them. The curves for variation of E.M.F. with temperature of copper-nickel and copper-iron couples are roughly a straight line and a parabola respectively. The differences between the actual curves and a selected straight line in the former case and a parabola in the latter case have been plotted against temperature. These difference curves show that the maximum variations occur, in the case of copper-iron, at 70°, 230°, and 370°. The temperature of inversion (cold junction 0° C.) is 536° C. and the neutral point is 262° C. In the case of copper-nickel, maximum variations occur at 70° and 340°, and there appears to be a small hysteresis effect at the latter point. The temperature of inversion does not occur within the limits of the experiments, and there is no neutral point. The E.M.F. curve for a nickel-iron couple up to 700° has been obtained from the two previous experimental curves by addition. Above this temperature direct observations have been taken. This curve is nearly linear up to 900°, at which point a decrease in E.M.F. occurs. Curves of thermoelectric power have been derived from the E.M.F. curves by drawing tangents, and these show that a considerable range of the copper-iron curve can be represented by straight lines, but that the remainder is approximately parabolic. The copper-nickel power curve can be represented by bits of straight lines. The Peltier-coefficient variation curve for iron-copper is at first parabolic and can then be made up of straight lines; for copper-nickel it can be made up of bits of parabolas. Considerable difficulty was experienced at high temperatures in getting concordant results owing to chemical changes and other effects. The experiments were therefore carried out under different conditions, and the results are discussed in the paper. In the resistance experiments a potentiometer method was employed, a manganin resistance coil immersed in an oil bath being used as a standard. The resistance of nickel increases with temperature almost parabolically up to 370°, when a change of slope occurs, and the resistance increases much less rapidly and almost linearly up to 1050°. In the case of iron, the resistance curve does not change its parabolic form till nearly 800°, when it becomes linear and remains so up to 1050°. The author concludes from his paper that the thermoelectric change in nickel-copper coincides approximately with the resistance change, but that no thermoelectric peculiarity exists for iron-copper at the temperature of the iron resistance change. Mr. A. Campbell said that with purer iron the change in thermoelectric properties might correspond with the change in resistance. Dr. Knott had performed experiments on nickel in 1886 and got results similar to those of the author. His results with thick wires were different to those with thin, probably because he did not exclude air and prevent oxidation. Mr. Campbell said that he had himself made experiments upon two samples of nickel differing in resistivity, and although their temperature coefficients were also different, the change in slope of the curve connecting resistance and temperature occurred at practically the same temperature in both specimens. Their thermoelectric powers were identical up to 300°, but above they differed slightly. Dr. D. K. Morris pointed out that the thermoelectric force, the resistance and the magnetic properties should be observed at the same time. In taking a thermoelectromotive force there must be a temperature gradient, and in the interesting parts of the curves differences of magnetic properties may arise and produce discrepancies. He drew attention to the caution which must be exercised in differentiating by drawing tangents except when the curves are smooth. Dr. Morris said the connection between resistance and magnetic qualities was interesting. The temperature coefficient of resistance of a magnetic body rises with temperature so long as the body is magnetic, but reverses when the body becomes non-magnetic. He asked for information on the subject. Prof. H. L. Callendar said he had followed the research with interest, and referred to the experimental difficulties, especially at high temperatures. He should like to have said something in reply to Dr. Morris, but he was afraid the subject was a large one and might well be discussed at some future meeting. There were several points to clear up, and the fact that the curves described cannot be represented by straight lines or parabolas showed that the subject was beyond the range of a simple theory. The chairman suggested that it might be well to re-examine more carefully some of the curves which are accepted as straight lines and on which there is no complication due to magnetic properties. He hoped the author and others would continue working at this subject. Mr. E. P. Harrison, in reply to Dr. Morris, said he thought the number and accuracy of his observations justified him in drawing tangents to form his power and Peltier-effect curves.—A paper on asymmetry of the Zeeman effect, by Mr. G. W. Walker, was read by the secretary. Prof. Voigt predicted an asymmetry of the normal triplet, which has been verified by Zeeman. The author has considered the subject mathematically, and finds that asymmetry may arise as a second order term due to the magnetic field. The asymmetry would be more distinct the greater the field, which is opposed to the theory of Voigt. By giving numerical values to the symbols it is shown that the effect is extremely small. The author points out that his theory can provide an explanation of why a line may not be resolvable.

PARIS.

Academy of Sciences, October 21.—M. Bouquet de la Grye in the chair.—The junction of a closed network of triangulation, by M. P. Hatt.—Researches on the mummified fishes of ancient Egypt, by MM. Lortet and Hugounenq. A description and chemical analyses of mummified specimens of *Lates niloticus*. The ash consisted largely of common salt and silicates. The fish are in a wonderful state of preservation, they appear to have been enclosed in a mixture of clay and sand impregnated with a large proportion of alkaline salts, especially sodium chloride.—On a new layer of mammifers of the middle Eocene at Robiac, near Saint-Mamert, by MM. Ch. Déperet and G. Carrière. An account of the discovery of a rich deposit of Eocene vertebrates at Robiac. The species identified include *Lophiodon rhinocerodes* and *isselensis*, *Paloplotherium magnum* and *lugdunense*, *Pachynolophus Duvali*, *Anchilophus Desmaresti*, and *Hyopotamus Gresslyii*.—The limit of chemical reactions and that of the product PV in gases, by M. A Ponsot.—The diameters of Jupiter obtained with the Brunner Equatorial of the Observatory of Lyons. The influence of magnification, by M. J. Guillaume. The value obtained for the apparent diameters of this planet differed slightly according to the magnification employed. A comparison of measurements of these diameters taken at different times by various astronomers shows that this effect is general.—On secondary chains, by M. G. Kœnigs.—On groups of substitutions, by M. G. A. Miller.—On linear differential equations of the second order with algebraical coefficients of the second and third species, by M. Paul J. Suchar.—On two particular classes of congruences of Ribaucour, by M. A. Demoulin.—On the variations of magnetisation in a cubical crystal, by M. Wallerant.—Action of the pyridine bases upon the tetra-halogen quinones, by M. Henry Imbert. The action of the pyridine bases upon chloranil and bromanil has been previously described. It is now shown that the resulting compounds still possess the quinonic function, as on reducing with sulphurous acid, hydroquinones are undoubtedly produced. The isolation and properties of the pyridyl compound are described.—On the oxidation of the benzene hydrocarbons by means of manganese peroxide and sulphuric acid, by M. H. Fournier. Toluic aldehyde was obtained as the oxidation product of ortho-xylene with these reagents. One of the methyl groups in pseudocumene was similarly oxidised to the aldehyde grouping, paracymene behaving similarly. With ethylbenzene the chief product was acetophenone, a little benzaldehyde being also produced.—The action of ammonia on benzyl chloride and on the conditions of formation of benzylamine, by M. René Dhommée. A study of the conditions under which the best yield of benzylamine can be obtained.—On the amine derived from the supposed binaphthylene glycol, by M. R. Fosse.—The nitro-derivatives of arabite and rhamnite; the constitution of certain nitrous esters, by MM. Leo Vignon and F. Gerin. The penta-nitro-derivative of arabite and the penta-nitro-rhamnite both readily reduce an alkaline copper solution. The cause in the differences in reducing power of various nitro-derivatives is accounted for by the authors by supposing a difference in constitution.—On glycerophosphorous acid and the glycerophosphites, by MM. Auguste Lumière, Louis Lumière and F. Perrin. A study of the acids and salts resulting from the action of phosphorus trichloride upon glycerine.—On a new microsporidium, *Pleistophora mirandellae*, a parasite of the ovary of *Alburnus mirandella*, by MM. C. Vaney and A. Conte.—Seasonal histolysis, by M. G. Bohn.—On some ferns with heterospores, by M. B. Renault.—The development of the embryo in the ivy (*Hedera helix*), by M. L. Ducamp. In the formation of the radicular cone the central cylinder remains apart from the suspender.—Retinal inertia relative to the sense of form, by MM. Andre Broca and D. Sulzer.

DIARY OF SOCIETIES.

THURSDAY, OCTOBER 31.

ROYAL SOCIETY, at 4.30.—Special Joint Meeting with the Royal Astronomical Society, to receive Preliminary Reports on the Solar Eclipse of 1901.

CHEMICAL SOCIETY, at 8.30.—The Frankland Memorial Lecture: Prof. H. E. Armstrong, F.R.S.

FRIDAY, NOVEMBER 1.

GEOLOGISTS' ASSOCIATION, at 8.—A Conversazione in the Library of University College, Gower Street.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Adjourned Discussion on the Second Gas-Engine Research Report by Prof. F. W. Burstall.

MONDAY, NOVEMBER 4.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Rapid and Approximate Estimation of Free Oxygen in Sewage Effluents and Waters: Prof. W. Ramsay, F.R.S.—Phthalic Glyceride: Watson Smith.—Notes on the Manufacture of Varnish by the Pressure Process: A. J. Smith.

TUESDAY, NOVEMBER 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Address by Mr. Charles Hawksley, President, and Presentation of Medals and Prizes awarded by the Council.

WEDNESDAY, NOVEMBER 6.

GEOLOGICAL SOCIETY, at 8.—On an Altered Siliceous Sinter from Builth: Frank Rutley.—Note on a Submerged and Glaciated Rock-Valley recently exposed to view in Caermarthenshire: T. Codrington.—On the Clarke Collection of Fossil Plants from New South Wales: E. A. Newell Arber.

ENTOMOLOGICAL SOCIETY, at 8.

THURSDAY, NOVEMBER 7.

LINNEAN SOCIETY, at 8.—On the Life-history of the Black-currant Mite (*Phytoptus ribis*): Mr. Warburton and Miss Embleton.—Notes on the types of Species of *Carex* in Boott's Herbarium: C. B. Clarke, F.R.S.

RÖNTGEN SOCIETY, at 8.30.—Presidential Address: Herbert Jackson.

CHEMICAL SOCIETY, at 8.—Note on the Non-existence of a Higher Oxide of Hydrogen than the Di-oxide: Prof. W. Ramsay, F.R.S.—The Electrolytic Reduction of Nitrourea: G. W. F. Holroyd.—(1) The Constitution of Pilocarpine, III.; (2) A New Synthesis of α-Ethyl Tricarballylic Acid: H. A. D. Jowett.—The Action of Nitric Acid on Methyl Dimethylacetoacetate: Prof. W. H. Perkin, F.R.S.—(1) An Incrustation from the Stone Gallery of St. Paul's Cathedral; (2) Note on Asbestos: E. G. Clayton.—Liquid Nitrogen Peroxide as a Solvent: Prof. P. F. Frankland, F.R.S., and R. C. Farmer.

FRIDAY, NOVEMBER 8.

ROYAL ASTRONOMICAL SOCIETY, at 5.

NOTICE.

THE ISSUE OF

NATURE

FOR THURSDAY NEXT, JUNE 13, WILL CONTAIN THE

INDEX

TO VOLUME LXIII.

ITS PRICE WILL BE ONE SHILLING.

Advertisements intended for insertion in this Number should reach the Publishers by TUESDAY, JUNE 11.

OFFICE OF "NATURE,"
ST. MARTIN'S STREET, LONDON, W.C.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE,

BURLINGTON HOUSE, LONDON, W.

The next ANNUAL MEETING of the ASSOCIATION will be held at GLASGOW, commencing on WEDNESDAY, SEPTEMBER 11.

PRESIDENT-ELECT:
Prof. A. W. RÜCKER, D.Sc., LL.D., Sec.R.S.

Information about local arrangements may be obtained on application to the LOCAL SECRETARIES, 30 George Square, Glasgow.

G. GRIFFITH, Assistant General Secretary.

UNIVERSITY OF BIRMINGHAM.

FACULTY OF SCIENCE.
RESEARCH SCHOLARSHIPS.
Each of the value of about £96.

(Founded by the late T. AUBREY BOWEN, Esq., of Melbourne, Australia).

(*a*) Two BOWEN SCHOLARSHIPS in ENGINEERING.
(*b*) One BOWEN SCHOLARSHIP in METALLURGY.
(*c*) Three PRIESTLEY SCHOLARSHIPS in CHEMISTRY.

The object of these Scholarships is to encourage Higher Work and Research in Scientific Professional Engineering and in Chemical and Metallurgical Science.

Applications, supported by details of educational training and references to former teachers and others, should be sent to the REGISTRAR on or before July 1, 1901. The Awards will be made in September next, and the Scholarships will be tenable during the Session 1901-2.

Further particulars may be obtained on application to the REGISTRAR.

COUNTY BOROUGH OF SUNDERLAND.

TECHNICAL COLLEGE.

Applications are invited for Four Lectureships in the following subjects at the above College, which will be opened for the first time in the ensuing Autumn:—

I.—Mechanical and Civil Engineering.
II.—Physics and Electrical Engineering.
III.—Chemistry.
IV.—Modern Languages (German and French).

Salary, £200 per annum each, with prospect of advance in salary and status. No Fees. Age not to exceed 35 years. Candidates must be qualified to give instruction equal in standard to that of a University College.

For further particulars, written application should be made to the PRINCIPAL.

Applications, with a duplicate set of not more than five testimonials, to be sent by post, addressed to "The Principal of the Technical College, Town Hall, Sunderland," to be delivered there not later than June 28, 1901.

By Order,
FRAS. M. BOWEY,
Town Clerk.

Town Hall, Sunderland,
June, 1901.

CITY OF NORWICH TECHNICAL INSTITUTE.

The Technical Instruction Committee of the Corporation of Norwich invite applications for the following Appointments:—

LECTURER IN CHEMISTRY. Salary, £150 per annum. Candidates must be under 26 years of age, and specially qualified in this subject.

LECTURER IN BUILDING CONSTRUCTION, and allied subjects. Salary, £150 per annum. Candidates must be under 30 years of age.

The last date for sending in applications for either Appointment is June 22.

Intending candidates should send a stamped addressed foolscap envelope to the undersigned for further particulars and application form.

WILLIAM GANNON, M.A.,
Principal.

June 4, 1901.

THE INDIAN GOVERNMENT requir

the services of an ELECTRICAL ENGINEER as PROFESSO on the Staff of the CIVIL ENGINEERING COLLEGE, SIBPU His duties will be to Lecture on Electrical and Mechanical Enginee ing, to Superintend the Workshops, and to be in general charge of t Dynamo House attached to the College. The Salary will be:—

Rs. 500-50-700 a month during the first five years,
Rs. 750-50-1000 a month during the next five years,
and eventually Rs. 1100 a month,

and until free quarters are provided a grant of Rs. 75 a month will allowed. Applications should be addressed to the SECRETARY, Publ Department, India Office, London, and should be received not lat than June 29 next.

India Office, Whitehall, May 28, 1901.

UNIVERSITY OF BIRMINGHAM.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE,

BURLINGTON HOUSE, LONDON, W.

The next ANNUAL MEETING of the ASSOCIATION will be held at GLASGOW, commencing on WEDNESDAY, SEPTEMBER 11.

PRESIDENT-ELECT:

Prof. A. W. RÜCKER, D.Sc., LL.D., Sec.R.S.

Information about local arrangements may be obtained on application to the LOCAL SECRETARIES, 30 George Square, Glasgow.

G. GRIFFITH, Assistant General Secretary.

BOROUGH OF LONGTON.

SUTHERLAND TECHNICAL INSTITUTE AND LONGTON HIGH SCHOOL.

HEADMASTER ... GEORGE GEORGE, F.I.C., F.C.S.

The Governors invite Applications for the following posts:—

1. MISTRESS FOR COOKERY AND DRESSMAKING.

   A Lady who has had some teaching experience, and is able to take some English subjects in a Junior Form, desirable. Commencing Salary, £60 to £70 per annum, according to qualifications.

2. ASSISTANT MISTRESS FOR ART SUBJECTS.

   One holding Art Class Teacher's Certificate, and qualified to give instruction in the Advanced Stage of Practical Plane and Solid Geometry. Every facility given to successful candidate for working for Art Master's Certificate. Salary, £60 to £70 per annum, according to qualifications.

3. ASSISTANT SCIENCE MASTER FOR PHYSICS AND CHEMISTRY.

   Good practical man desired, and one who has had experience in an Organised Science School. Salary, £120 per annum.

Applications, stating age, where educated, teaching experience and qualifications to teach above-mentioned subjects (and others if any), and enclosing copies of three recent Testimonials, to be sent to the undersigned, not later than July 20.

Successful Candidates will be required to teach both in the Day School of Science as well as in the Evening Technical School.

W. T. COPE,
Secretary to the Technical Instruction Committee.

Court House, Longton, Staffs.,
June 26, 1901.

CITY AND COUNTY BOROUGH OF BELFAST.

APPOINTMENT OF ART MASTERS.

The Library and Technical Instruction Committee desire to obtain the services of Four Masters for their School of Art, viz.:—

A HEAD MASTER, who must be a specialist either in Design or in Drawing from Life. Salary, £350.

A SECOND MASTER, with special experience in either of the before-named branches. Salary, £240.

A MASTER for PAINTING and STILL LIFE. Salary, £200.

A MODELLING MASTER. Salary, £160.

Information as to conditions of appointment, &c., may be obtained on application to the PRINCIPAL OF THE MUNICIPAL TECHNICAL INSTITUTE, Town Hall, Belfast, with whom applications, stating age, present engagement, &c, with copies of not more than three testimonials, should be lodged not later than Wednesday, July 17.

Canvassing will be a disqualification.

SAMUEL BLACK,
Town Clerk.

July 3, 1901.

UNIVERSITY OF TORONTO.

Applications, accompanied by testimonials, will be received by the undersigned until September 15, for Professorships in the following subjects:—

(1) GEOLOGY, including PALÆONTOLOGY.

(2) MINERALOGY and PETROGRAPHY.

The appointments will be made in the first instance for a period of three years, after which time they will be made permanent if the services of the appointees have been satisfactory. The initial salary is $2500, increasing by annual increments of $100 until a maximum of $3200 is reached. For further information apply to PRESIDENT LOUDON, c/o the High Commissioner for Canada, 17 Victoria Street, S.W.

RICHARD HARCOURT, Minister of Education.

Toronto, Ontario (Canada), June 1901.

WEST HAM MUNICIPAL TECHNICAL INSTITUTE.

WANTED, ASSISTANT DEMONSTRATOR in Physical Laboratory Classes for the Session 1901-1902. Two evenings a week.

F r further particulars apply to the PRINCIPAL, Municipal Technical ... titute, West Ham, E., to whom all applications must be made.

RATHMINES URBAN DISTRICT.

TECHNICAL SCHOOLS PRINCIPAL WANTED.

Notice is hereby given that the Technical Instruction Committee of Rathmines are prepared to consider applications from Candidates for the position of HEAD-MASTER or PRINCIPAL of the Technical Schools about to be established in the district. The Technical Schools will be mainly of a high-class Commercial type.

The salary will be £400 per annum.

No person need apply who has not had some scientific or technical training, as well as experience as teacher, in a Technical School.

Particulars as to duties, terms of appointment, &c., may be had on application to me.

Applications, accompanied by copies of testimonials, stating age, qualifications, and experience, should be sent to me before MONDAY, July 8, 1901.

By Order,
F. P. FAWCETT, Secretary.

Town Hall, Rathmines, June 21, 1901.

BALLYMENA URBAN DISTRICT COUNCIL.

MUNICIPAL TECHNICAL SCHOOL.

The Urban Council of Ballymena (population about 11,000) is promoting a Scheme of Technical Instruction under the provisions of the Agriculture and Technical Instruction (Ireland) Act, 1899. A HEADMASTER is Wanted whose duties will involve the organisation of Classes, the equipment of a suitable School, and advising the Committee on all subjects of Technical Instruction. The principal industries of the town are Spinning and Weaving, Ironfounding, Boot-making and Coach-building. The Headmaster must be qualified to give instruction in some Science and Art Subjects, as well as in some Subjects of Applied Science and Art on Trade Subjects. Probable salary, £250 per annum.

Applications, accompanied by nine copies of testimonials, to be forwarded to the TOWN CLERK, Ballymena, County Antrim, not later than July 15.

By Order,

HENRY O'HARA.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

(A CONSTITUENT COLLEGE OF THE UNIVERSITY OF WALES.)

AGRICULTURAL CHEMISTRY.

Applications are invited for the post of ASSISTANT LECTURER AND DEMONSTRATOR IN AGRICULTURAL CHEMISTRY. Salary £120. Candidates will be required to show a sound general knowledge of Inorganic and Organic Chemistry.

Applications and Testimonials should be received not later than Monday, September 2, by the undersigned, from whom further particulars may be obtained.

JOHN EDWARD LLOYD, M.A.,
Secretary and Registrar.

Bangor, June 19, 1901.

CROYDON COUNTY POLYTECHNIC, CROYDON.

DEPARTMENT OF ELECTRICAL ENGINEERING.

The Committee require the services of an ASSISTANT LECTURER and DEMONSTRATOR in this Department. The person appointed will be required to attend on three evenings each week, and must be qualified to lecture in at least one branch of Electrical Engineering. Salary, £50 for the Session of about 30 weeks.

Applications with copies of testimonials must be sent to the undersigned, from whom further particulars of the appointment may be obtained, not later than Wednesday, July 10, 1901.

S. W. BICKELL, Secretary.

June 24, 1901.

ROYAL ALBERT MEMORIAL COLLEGE, EXETER.

The Governors will appoint a LECTURER as Head of the Department of MATHEMATICS and APPLIED PHYSICS.

Candidates must be graduates in honours of some English University and should have had experience of Class teaching and of Organising work.

Salary, £250 a year, with share of the Fees of Day Students in his department.

Canvassing the Governors will disqualify a candidate.

Applications and copies of testimonials should be sent before July 20 to the PRINCIPAL.

MUNICIPAL TECHNICAL SCHOOL, LEICESTER.

WANTED, in September, an INSTRUCTOR in ENGINEERING SUBJECTS. Day and Evening Classes. Salary, £150 per annum.

Apply to

ALFRED T. NEWBY,
Secretary.

UNIVERSITY OF BIRMINGHAM.

1901–2.

DEPARTMENT OF ENGINEERING.

CHANCE CHAIR OF ENGINEERING.

Professor: F. W. BURSTALL, M.A., Cantab., M.I.C.E., M.I.M.E.
Lecturer on Mechanical Engineering: Vacant.
Lecturer on Electrical Engineering: D. K. MORRIS, Ph.D., A.I.E.E.
Assistant Lecturer: F. H. HUMMEL, A.M.I.C.E.
Demonstrator: JAMES P. WOOD, B.E.
Instructor in Wood Work: T. D. GARSCADDEN.
Instructor in Iron Work: F. H. A. HALL.

The full Courses extend over four years, and Students who enter after Matriculation and who pass successfully the Examinations at the end of each year will be entitled to the degree of Bachelor of Science in the branch of Engineering to which they devote themselves.

THE TECHNICAL ENGINEERING CLASSES INCLUDE:—

LECTURES on the Strength of Materials, Theory of Steam, Gas and other Heat Engines, Hydraulics, Machine Design, Strength of Structures, Distribution of Power.

DRAWING: Design of Tools, Prime Motors, Dynamos, and other forms of Machinery.

COURSES IN CIVIL ENGINEERING, including Constructional Work in Masonry and Steel, Railway Work, Dams, Bridges, and Water Engineering.

FIELD WORK: Practical Surveying in the Field throughout the Summer Term.

ENGINEERING LABORATORY: Determination of the Strength of Materials, including Compressive, Bending, Tensile, and Torsion Tests, Experimental Study of the Steam Engine and Boiler, Frictional Efficiency Tests, the Flow of Water over Weirs and through Orifices, &c.

LECTURES and DEMONSTRATIONS on all Branches of Electrical Engineering.

ELECTRICAL LABORATORY: Testing of Continuous and Alternate Current Machinery. Electrical Instruments, Meters, Lamps, and Batteries. Insulation and Magnetic Testing Work.

THE COURSES ALSO INCLUDE:—

Mathematics	Professor R. S. HEATH, M.A., D.Sc.
Physics	Professor J. H. POYNTING, D.Sc., F.R.S.
Chemistry	Professor PERCY F. FRANKLAND, B.Sc., Ph.D., F.R.S.
Geology...	Professor C. LAPWORTH, LL.D., F.R.S., F.G.S.
Metallurgy	Lecturer: G. MELLAND, B.Sc., A.R.S.M.

The SESSION 1901–2 commences on Tuesday, October 1, 1901.

Professor Burstall will attend to consult with intending students on October 1 from 10 a.m. to 1 p.m.

For DETAILED SYLLABUS, with full particulars of Fees, Scholarships, &c., apply to the Secretary of the University.

QUEEN'S COLLEGE, GALWAY.

The Matriculation Examination of Session 1901–1902 commences on October 18. Matriculation Certificates of any University within the United Kingdom are accepted.

All Lectures, Scholarships, Exhibitions, and Prizes are open to Students of either sex.

The Scholarship Examinations in Arts, Medicine, and Engineering commence on October 21.

DEPARTMENTS OF

SCIENCE, MEDICINE, AND ENGINEERING.

MATHEMATICS ...	Prof. Alfred C. Dixon, M.A., Sc.D., F.R.U.I., late Fellow of Trinity College, Cambridge

REGISTRAR,
Queen's College, Galway.

WANTED.—Berth in Chemical or Physical

Laboratory (former preferred), 14 years' experience. Expert Glass-blower.—Apply, "S. C. V.," Nature Office.

THE DAVY-FARADAY RESEARCH LABORATORY

OF THE

ROYAL INSTITUTION.

DIRECTORS:

The Right Hon. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S.
Professor DEWAR, M.A., LL.D., F.R.S.

Superintendent of the Laboratory:
Dr. ALEXANDER SCOTT, M.A., D.Sc., F.R.S.

This Laboratory was founded by Dr. Ludwig Mond, F.R.S., as a Memorial of Davy and Faraday, for the purpose of promoting, by original research, the development and extension of Chemical and Physical Science.

The Laboratory is open free of charge to Workers of either sex, and any nationality, prosecuting individual investigations; and the extensive collection of Physico-Chemical Apparatus presented by the Founder is available for their use, together with such materials, chemicals, electricity, &c., as the Directors may authorise.

Assistants and a trained mechanician are attached to the Laboratory to aid Workers in the prosecution of their researches.

All persons desiring to be admitted as Workers must send evidence of scientific training, qualification, and previous experience in original research, along with a statement of the nature of the investigation they propose to undertake.

Michaelmas Term.—Monday, October 7, to Saturday, December 14.
Lent Term.—Monday, January 6, to Saturday, March 22.
Easter Term.—Monday, April 14, to Saturday, July 26.

Forms of Application can be had from the Assistant Secretary, Royal Institution, Albemarle Street, W.

(VICTORIA UNIVERSITY.)

UNIVERSITY COLLEGE, LIVERPOOL.

DEPARTMENT OF ENGINEERING.

Session 1901–1902 commences October 3. Complete Courses of Instruction are arranged in

(1) Civil Engineering.
(2) Mechanical Engineering.
(3) Electrical Engineering.

These Courses enable Students to qualify for University Degrees, and for the College Certificates in Engineering. They comprise, in addition to special Engineering Lectures and Laboratory Work, instruction in Mathematics, Physics, Electrotechnics, and Chemistry.

Harrison Professor of Engineering	H. S. Hele-Shaw, LL.D., F.R.S., M.Inst.C.E.
Lyon Jones Professor of Experimental Physics	L. R. Wilberforce, M.A., Trinity College, Cambridge.
Professor of Mathematics	F. S. Carey, M.A., late Fellow of Trinity College, Cambridge.
Grant Chair of Chemistry	J. Campbell Brown, D.Sc., F.I.C.
Electrotechnics	E. W. Marchant, D.Sc.

The special Engineering Prospectus can be obtained on application to the Secretary.

VICTORIA UNIVERSITY.

THE YORKSHIRE COLLEGE, LEEDS.

The 28th Session of the Department of Science, Technology, Arts and Law, and the 71st Session of the School of Medicine, will begin on October 1, 1901.

The Classes prepare for the following Professions: Chemistry, Civil, Mechanical, Electrical, and Sanitary Engineering, Mining, Textile Industries, Dyeing, Art, Leather Manufacture, Agriculture, School Teaching, Law, Medicine, and Surgery.

University Degrees are also conferred in the Faculties of Arts, Science, Law, Medicine, and Surgery.

Lyddon Hall has been established for Students' residence.

Prospectus of any of the above may be had from the Registrar of the College.

THE YORKSHIRE COLLEGE, LEEDS.

DEPARTMENTS OF CIVIL, MECHANICAL AND ELECTRICAL ENGINEERING.

The Twenty-eighth Session will begin October 1, 1901.
Prospectus may be obtained from the Registrar.

UNIVERSITY COLLEGE, LIVERPOOL.

DEPARTMENT OF ENGINEERING.

Session 1901–1902 commences October 3. Complete Courses of Instruction are arranged in

(1) Civil Engineering.
(2) Mechanical Engineering.
(3) Electrical Engineering.

These Courses enable Students to qualify for University Degrees, and for the College Certificates in Engineering. They comprise, in addition to special Engineering Lectures and Laboratory Work, instruction in Mathematics, Physics, Electrotechnics, and Chemistry.

Harrison Professor of Engineering	H. S. Hele-Shaw, LL.D., F.R.S., M.Inst.C.E.
Lyon Jones Professor of Experimental Physics	L. R. Wilberforce, M.A., Trinity College, Cambridge.
Professor of Mathematics	F. S. Carey, M.A., late Fellow of Trinity College, Cambridge.
Grant Chair of Chemistry	J. Campbell Brown, D.Sc., F.I.C.
Electrotechnics	E. W. Marchant, D.Sc.

The special Engineering Prospectus can be obtained on application to the Secretary.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1901-1902 will open on WEDNESDAY, October 2, when the prizes will be distributed at 3 p.m. by Major-General Sir Ian Hamilton, K.C.B., in the Governors' Hall.

St. Thomas's Hospital being one of the Medical Schools of the University of London, provision is made for the courses of study prescribed for the Preliminary Scientific, Intermediate and Final Examinations in Medicine.

Three Entrance Scholarships will be offered for competition in September, viz., one of £150 and one of £60 in Chemistry and Physics, with either Physiology, Botany, or Zoology, for first year's Students; one of £50 in Anatomy, Physiology, Chemistry (any two), for third year's Students from the Universities.

Scholarships and money prizes are awarded at the Sessional Examinations, a well as several medals.

All Hospital Appointments are open to Students without charge.

Club Rooms and an Athletic Ground are provided for Students.

The School Buildings and the Hospital can be seen on application to the Medical Secretary.

The Fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and Special Arrangements are made for Students entering from the Universities and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of Local Medical Practitioners, Clergymen, and others who receive Students into their houses.

For Prospectus and all particulars apply to Mr. Rendle, the Medical Secretary.

H. G. TURNEY, M.A., M.D. Oxon., Dean.

UNIVERSITY OF BIRMINGHAM.

FACULTY OF MEDICINE.

Regulations concerning the various Degrees conferred by this University, and the requisite Courses of Instruction given at the same, and at the Hospitals of the City, will be found in the Syllabus of the Medical Faculty, which can be obtained Gratis on application to Messrs. Cornish Brothers, Booksellers, New Street, Birmingham, or to Geo. H. Morley, Secretary of the University.

The Syllabus gives all information as to

I. DEGREES IN MEDICINE.
II. DEGREE AND DIPLOMA IN PUBLIC HEALTH.
III. DEGREES IN DENTISTRY.

The WINTER SESSION will Commence on Tuesday, October 1.

The Dean (Professor Windle, M.D., D.Sc., F.R.S.) will see parents and Students on September 26, 27 and 30, between the hours of ten and one, also on October 1 and 2, at the same hours, and from two o'clock until three in the afternoon. The Courses of Instruction, though mainly arranged in accordance with the regulations of the University, qualify also for the examinations of other British Universities and for those of all the Licensing Corporations.

ALL DEGREES AND COURSES OF INSTRUCTION ARE OPEN TO MEN AND WOMEN ALIKE.

For information as to Entrance Scholarships see the Syllabus.

There are also Faculties of Science and Arts. Syllabuses, containing full particulars, are published separately.

THE LONDON SCHOOL OF TROPICAL MEDICINE

(UNDER THE AUSPICES OF HIS MAJESTY'S GOVERNMENT), CONNAUGHT ROAD, ALBERT DOCK, E.

In connection with the Hospitals of the Seamen's Hospital Society.

Sessions commence October 1, January 15, and May 1. For Prospectus, Syllabus, and other particulars, apply to the Secretary, P. Michelli, Esq., Seamen's Hospital, Greenwich, S.E.

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on October 1. Introductory Lecture, at 4 p.m., by Prof. J. Risien Russell, M.D., F.R.C.P., Professor of Medical Jurisprudence.

The Examinations for the Entrance Scholarships and Medical Exhibitions will commence on September 25.

The Annual Dinner will be held on October 1, Sir Richard Douglas Powell, Bart., in the Chair.

Scholarships, Exhibitions, and Prizes of the value of £800 are awarded annually.

In University College Hospital about 3000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six Appointments, eighteen being resident (as House Surgeon, House Physician, Obstetric Assistant, &c.), are filled up by competition during the year, and these, as well as all Clerkships and Dresserships, are open to Students of the Hospital without extra fee. Resident Officers receive free board and lodging.

Prospectuses, with full information as to Classes, Prizes, &c., may be obtained from University College, Gower Street, W.C.

J. R. BRADFORD, M.D., D.Sc., F.R.S., Dean.
T. GREGORY FOSTER, Ph.D., Secretary.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.

PRELIMINARY SCIENTIFIC CLASS.

Systematic Courses of Lectures and Laboratory Work in the subjects of the Preliminary Scientific and Intermediate B.Sc. Examinations of the University of London will commence on October 1, and continue till July, 1902. Attendance on this Class counts as part of the Five Years' Curriculum.

Fee for the whole Course, £21, or £18 18s. to Students of the Hospital; or single Subjects may be taken.

There is a Special Class for the January Examination.

For further particulars apply to the Warden of the College, St. Bartholomew's Hospital, London, E.C.

A Handbook forwarded on application.

VICTORIA UNIVERSITY.

THE YORKSHIRE COLLEGE, LEEDS.

The 28th Session of the Department of Science, Technology, Arts and Law, and the 71st Session of the School of Medicine, will begin on October 1, 1901.

The Classes prepare for the following Professions: Chemistry, Civil, Mechanical, Electrical, and Sanitary Engineering, Mining, Textile Industries, Dyeing, Art, Leather Manufacture, Agriculture, School Teaching, Law, Medicine, and Surgery.

University Degrees are also conferred in the Faculties of Arts, Science, Law, Medicine, and Surgery.

Lyddon Hall has been established for Students' residence.

Prospectus of any of the above may be had from the Registrar of the College.

THE YORKSHIRE COLLEGE, LEEDS.

DEPARTMENTS OF CIVIL, MECHANICAL AND ELECTRICAL ENGINEERING.

The Twenty-eighth Session will begin October 1, 1901.

Prospectus may be obtained from the Registrar.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE,

BURLINGTON HOUSE, LONDON, W.

The next ANNUAL MEETING of the ASSOCIATION will be held at GLASGOW, commencing on WEDNESDAY, SEPTEMBER 11.

President-Elect:
Prof. A. W. RÜCKER, D.Sc., LL.D., Sec.R.S.

Information about local arrangements may be obtained on application to the Local Secretaries, 30 George Square, Glasgow.

G. GRIFFITH, Assistant General Secretary.

BRITISH MUSEUM.

The Reading Rooms will be Closed from Monday, September 2, to Thursday, September 5, inclusive.

British Museum, August 26, 1901.

E. MAUNDE THOMPSON, Director and Principal Librarian.

UNIVERSITY COLLEGE, SHEFFIELD.

Applications are invited for the post of JUNIOR DEMONSTRATOR IN CHEMISTRY, vacant by the appointment of Dr. Price to the Lectureship in Chemistry at Birmingham University. Salary, £100. Testimonials to be sent in before September 21.

For further information apply to the Registrar, University College, Sheffield.

For other Tutorial Advertisements see page ccviii.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

" To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 1662, Vol. 64] THURSDAY, SEPTEMBER 5, 1901. [Price Sixpence.

Registered as a Newspaper at the General Post Office.]

UNIVERSITY OF EDINBURGH.

Principal—**Sir WILLIAM MUIR, K.C.S.I., D.C.L., LL.D., Ph.D., &c.**

The WINTER SESSION opens on 15th October (Practical Anatomy 1st October), and closes on 22nd March. The SUMMER SESSION opens at the beginning of May, and closes about the middle of July.

FACULTY OF MEDICINE.

Dean—Professor A. R. SIMPSON, M.D.

The Faculty embraces thirteen Chairs and eight Lectureships; and attached to these Chairs there are about thirty Assistants and Demonstrators. Instruction is given in all the branches of Medical Science, viz.:—

Professors.

Chemistry—Alex. Crum Brown, M.D., D.Sc. LL.D.
Zoology—J. Cossar Ewart, M.D.
Botany—Isaac Bayley Balfour, M.D., D.Sc.
Physics—J. G. MacGregor, M.A.
Anatomy—Sir William Turner, M.B., D.C.L., LL.D.
Physiology—E. A. Schäfer, LL.D.
Materia Medica—T. R. Fraser, M.D., LL.D.
Pathology—William S. Greenfield, M.D.
Public Health—C. Hunter Stewart, M.D., D.Sc.
Forensic Medicine—Sir Henry D. Littlejohn, M.D., LL.D.
Medicine—John Wyllie, M.D., LL.D.
Surgery—John Chiene, M.D.
Midwifery—Alexander Russell Simpson, M.D.
Clinical Surgery—Thomas Annandale, M.D.
Clinical Medicine—T. R. Fraser, M.D., Wm. S. Greenfield, M.D., John Wyllie, M.D., A. R. Simpson, M.D. (on Diseases of Women).

University Lecturers.

Mental Diseases—T. S. Clouston, M.D.
Diseases of the Eye—G. A. Berry, M.B.
Clinical Instruction on Diseases of Children—Staff of Royal Hospital for Sick Children.
Embryology and Vertebrate Zoology—J. Beard, D.Sc.
Regional Anatomy—D. Hepburn, M.D.
Advanced Practical Physiology—T. H. Milroy, M.D., B.Sc.
Experimental Pharmacology—W. C. Sillar, M.B., B.Sc.
Pathological Bacteriology—J. M. Beattie, M.D.
Physics—C. G. Knott, M.A., D.Sc.
Diseases of the Larynx, Ear, and Nose—P. M'Bride, M.D.
Tropical Diseases—A. Davidson, M.D.
Diseases of the Skin—W. Allan Jamieson, M.D.

Practical Instruction is afforded, under the superintendence of the Professors, in Laboratories with the necessary appliances, and in Tutorial and Practical Classes connected with the above Chairs, and opportunities are afforded to Students and Graduates to extend their practical knowledge and engage in original research.

Opportunities for Hospital Practice are afforded at the Royal Infirmary, the Hospital for Sick Children, Maternity Hospital, the City Hospital, and the Asylum for the Insane. Upwards of 1500 beds are available for the Clinical Instruction of Students of the University.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh, viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.); and Diplomas in Special Branches of Medical and Surgical Practice may also be conferred on Graduates in Medicine and Surgery of the University.

The minimum Class Fees for M.B. and Ch.B., including Hospital Fee (£12) amount to about £115, and the Matriculation and Examination Fees to £28 7*s*. An additional Fee of £10 10*s*. is payable by those who proceed to M.D., and £10 10*s*. by those who proceed to Ch.M.

The annual value of the Bursaries, Prizes, Scholarships, and Fellowships in the Faculty of Medicine amounts to about £3600, and that of the other Bursaries, &c., tenable by Students of Medicine, amounts to about £1820.

Instruction is also given in Public Health, and the Degrees of B.Sc. and D.Sc. in Public Health are conferred by the University.

Residences for Students, Graduates, and others, situated within easy reach of the University, afford excellent board and lodging on very moderate terms.

Further information as to Matriculation, the Curricula of Study for Degrees, &c., may be obtained from the Dean of the Faculty of Medicine; or from the Clerk of Senatus; and full details are given in the University Calendar, published by James Thin, 55 South Bridge.

August, 1901.

By authority of the Senatus, L. J. GRANT, Secretary of Senatus.

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1901-2 will open on TUESDAY, OCTOBER 1.

DEPARTMENTS of PHYSICS, CHEMISTRY, and BIOLOGY.

PHYSICS .... Prof. E. Taylor Jones, D.Sc. Assistant Lecturers and Demonstrators, T. C. Baillie, M.A., D.Sc., and W. W. Firth, M.Sc.

CHEMISTRY ... Prof. J. J. Dobbie, M.A., D.Sc. Assistant Lecturer and Demonstrator, A. Lauder, B.Sc.

BIOLOGY ...... Botany—Prof. R. W. Phillips, M.A., D.Sc. ,, Assistant Lecturer and Demonstrator, J. Lloyd Williams. Zoology—Prof. Philip J. White, M.B., F.R.S.E.

The Classes and Laboratory Courses of this College are arranged to suit the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. The Lectures in Chemistry, Physics, Botany, and Zoology are recognised by the Universities of Edinburgh and Glasgow as qualifying for the Medical Degrees of those Universities. One *Annus Medicus* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are fully equipped for Study and Research, and in the Physical Department special provision has been made for the teaching of Electrical Engineering. A Special Course has been arranged in this subject.

Inclusive Tuition Fee, £11 1*s*.

LABORATORY FEES (per Term)

on the scale of £1 1*s*. for six hours a week, in each Department.

A considerable number of Scholarships and Exhibitions are open for competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the year's work.

For full information as to Courses, apply for Prospectus to the Secretary and Registrar,

J. E. LLOYD, M.A.

NORTHAMPTON INSTITUTE, CLERKENWELL, LONDON, E.C.

ENGINEERING DAY COURSES IN MECHANICAL, ELECTRICAL AND HOROLOGICAL ENGINEERING.

FULL DAY COURSES in the above subjects will commence on MONDAY, September 30, 1901. ENTRANCE EXAMINATION on WEDNESDAY and THURSDAY, September 25 and 26. Particulars of the Courses can be obtained on application at the Office of the Institute, or to

R. MULLINEUX WALMSLEY, D.Sc., Principal.

☞ *New Session commences 30th September.*

BIRKBECK INSTITUTION,

Breams Buildings, Chancery Lane, E.C.

Principal: G. ARMITAGE-SMITH, M.A.

Science Classes with Practical Work.

DAY AND EVENING COURSES for—

UNIVERSITY of LONDON.—B.Sc. Pass and Honours, Inter. Sci., Prelim. Sci., and Inter. M.B. (Chemistry) Examinations.

CONJOINT BOARD, DENTAL and **PHARMACEUTICAL EXAMINATIONS.**

COMPLETE DAY COURSE IN METALLURGY AND MINING.

HIGHLY EQUIPPED LABORATORIES, for—

CHEMISTRY, PHYSICS, BIOLOGY (ZOOLOGY and BOTANY) METALLURGY, GEOLOGY and MINERALOGY.

EVENING CLASSES in all BRANCHES of SCIENCE.

COUNTY BOROUGH OF SUNDERLAND TECHNICAL COLLEGE.

Owing to the large influx of Students at the above College, recently opened, additional teaching staff is required. Applications are therefore invited for the following posts:—

I. ASSISTANT LECTURER IN MATHEMATICS. Salary, £150 per annum.

II. DEMONSTRATOR IN PHYSICS AND ELECTRICAL ENGINEERING. Salary, £120 per annum.

III. DEMONSTRATOR IN CHEMISTRY. Salary, £120 per annum

IV. DEMONSTRATOR IN ENGINEERING. Salary, £120 per annum.

V. ASSISTANT LECTURER IN GERMAN. Salary, £120 per annum.

Prospect of advance in Salary.

Age not to exceed [illegible] years. *Candidates must be qualified to give instruction equal in standard to that of a University College.*

For further particulars, written application should be made to the Secretary

Applications, with a duplicate set of not more than five testimonials, to be sent by post, addressed to Secretary, Technical College, Sunderland, with the particular post applied for named in the bottom left-hand corner of the envelope, and to reach the College not later than Monday, November 4, 1901.

By order,
FRAS. M. BOWEY, Town Clerk.

Town Hall, Sunderland,
October 15, 1901.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS.

A Combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, DECEMBER 3, 1901.

Three Scholarships and three Exhibitions will be offered; with one exception the value of these endowments will be £80 a year.

The Subjects for Examination will be Physics, Chemistry, and Biology. Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to
Christ Church, Oxford. A. VERNON HARCOURT.

MAGDALEN COLLEGE, OXFORD.

NATURAL SCIENCE DEMYSHIPS AND EXHIBITIONS.

There will be an Examination at this College, commencing on December 10, 1901, with a view to electing to Two or More Demyships and Exhibitions in Natural Science.

Persons will be eligible for the Demyships who will not have exceeded the age of nineteen years on the day of Election, December 19, 1901, and for the Exhibitions who will not have exceeded the age of twenty-one years on the day of Election, December 19, 1901.

Candidates for these Demyships and Exhibitions will be required to pass such an Examination in Classics and Mathematics as will show their ability to pass hereafter in Responsions or an equivalent Examination.

For particulars of the Examination apply to the President, or the Natural Science Tutor, Magdalen College, who will forward a printed circular of details.

SIR JOHN CASS'S TECHNICAL INSTITUTE.

Principal: CHARLES A. KOHN, M.Sc., Ph.D.

The Governors of the Sir John Cass Foundation invite applications for the post of HEAD of the DEPARTMENT of PHYSICS and MATHEMATICS. Salary £250.

Applications, with copies of not more than three recent testimonials, must be sent in not later than November 9, addressed to the undersigned, from whom full details of the appointment may be obtained.

W. H. DAVISON,
Clerk to the Foundation,
Jewry Street, Aldgate, E.C.

BOROUGH OF SHREWSBURY.

The Technical Instruction Committee invite APPLICATIONS for the Post of ASSISTANT ART MASTER, qualified to teach Model, Freehand, and Geometrical Drawing. Applicants must have passed 1st Class in Advanced Building Construction (or Honours), Science and Art Department. Salary, £80, rising £10 per annum to £100, with liberty to accept employment under the County Council, or otherwise, at such times as not to interfere with duties at the Technical School, but subject to approval by the Committee. Personal canvassing will disqualify.

Applications, stating qualifications, when applicant could commence his duties, and with copies of testimonials (which will not be returned), marked "Art," to be sent not later than November 1, 1901, to

J. WILLIAMS, Secretary.

Guildhall, Shrewsbury, October 15, 1901.

BIRKBECK INSTITUTION,
